<sup>103</sup> **Executive summary**

<sup>104</sup> **Stock**

<sup>105</sup> This assessment reports the status of the China rockfish (*Sebastodes nebulosus*) resource in  
<sup>106</sup> U.S. waters off the coast of California, Oregon, and Washington using data through 2014.  
<sup>107</sup> China rockfish are modelled with three independent stock assessments to account for spatial  
<sup>108</sup> variation in exploitation history as well as regional differences in growth and size composition  
<sup>109</sup> of the catch. The northern area model is defined as Washington state Marine Catch Areas  
<sup>110</sup> (MCAs) 1-4. The central area model spans from the Oregon-Washington border to 40°10'  
<sup>111</sup> N. latitude. The southern area model spans 40°10' N. latitude to the U.S.-Mexico border.  
<sup>112</sup> However, very little catch of China rockfish occurs south of Point Conception, California  
<sup>113</sup> (34°27' N. latitude).

<sup>114</sup> **Catches**

<sup>115</sup> China rockfish are most often caught by hook-and-line (both recreational and commercial  
<sup>116</sup> fisheries) as well as by traps in the commercial live-fish fishery. Although China rockfish  
<sup>117</sup> were not a major target species, the commercial rockfish fishery along the U.S. Pacific West  
<sup>118</sup> Coast developed in the late 1800s and early 1990s. Available estimates of China rockfish  
<sup>119</sup> catch in California begin in the early 1900s, along with small commercial catches in Oregon  
<sup>120</sup> until recreational landings began to increase in the early 1970s (Figures a-c). Reconstructed  
<sup>121</sup> recreational landings of China rockfish in the northern assessment begin in 1967. As of  
<sup>122</sup> 1995, Washington has prohibited commercial nearshore fixed gear in state waters and does  
<sup>123</sup> not have a historical reconstruction of China rockfish commercial landings. The majority of  
<sup>124</sup> commercial removals of China rockfish are now landed by live-fish fisheries in California and  
<sup>125</sup> southern Oregon. The magnitude of total removals over the last 10 years peaked in 2009  
<sup>126</sup> (35.52 mt) and has been decreasing since then. In recent years, California has the largest  
<sup>127</sup> removals of the three states (dominated by the recreational fleet) with smallest removals  
<sup>128</sup> coming from the Oregon recreational fleet (Table a).

<sup>129</sup> The nearshore live-fish fishery developed in California in the late 1980s and early 1990s and  
<sup>130</sup> extended into Oregon by the mid-1990s, driven by the market prices for live fish. Northern  
<sup>131</sup> Oregon (north of Florence) does not contribute significantly to the live-fish fishery (maximum  
<sup>132</sup> removal of 0.02 mt) as the market for this sector of the fishery is centered in California.  
<sup>133</sup> Catches from the live-fish fishery in southern Oregon (south of Florence) has composed the  
<sup>134</sup> majority of the catch in that state since 1999, and peaked in 2002. In California, the landings  
<sup>135</sup> of live fish begin exceeding the landings of dead fish south of 40°10' N. latitude in 1998 and  
<sup>136</sup> north of 40°10' N. latitude in 1999; and the pattern continues through 2014.

<sup>137</sup> The historical reconstruction of landings from the recreational fishery for China rockfish in  
<sup>138</sup> California goes back to 1928, and the fishery began significantly increasing in the late 1940s.  
<sup>139</sup> The recreational catches in California are significantly higher than the commercial catches,

<sup>140</sup> and have decreased in the last five years (Table a). Recreational catches in California peaked  
<sup>141</sup> in 1987 at 53.29 mt and have declined to roughly 10-20 mt per year over the last 10 years.  
<sup>142</sup> The trend is opposite in Oregon, with the magnitude of the commercial landings greater than  
<sup>143</sup> the recreational landings. The historical landings from the recreational fleet in Oregon start  
<sup>144</sup> in 1973 at 0.86 mt, peak in 1983 at 6.07 mt and again in 1993 at 6.04 mt. The recreational  
<sup>145</sup> catches over the last 10 years in Oregon have ranged from 1.67 mt in 2014 to 3.66 mt in 2007.  
<sup>146</sup> Recreational landings in Washington peaked in 1992 (7.98 mt) and have remained between  
<sup>147</sup> 2-4 mt from 2005-2014.

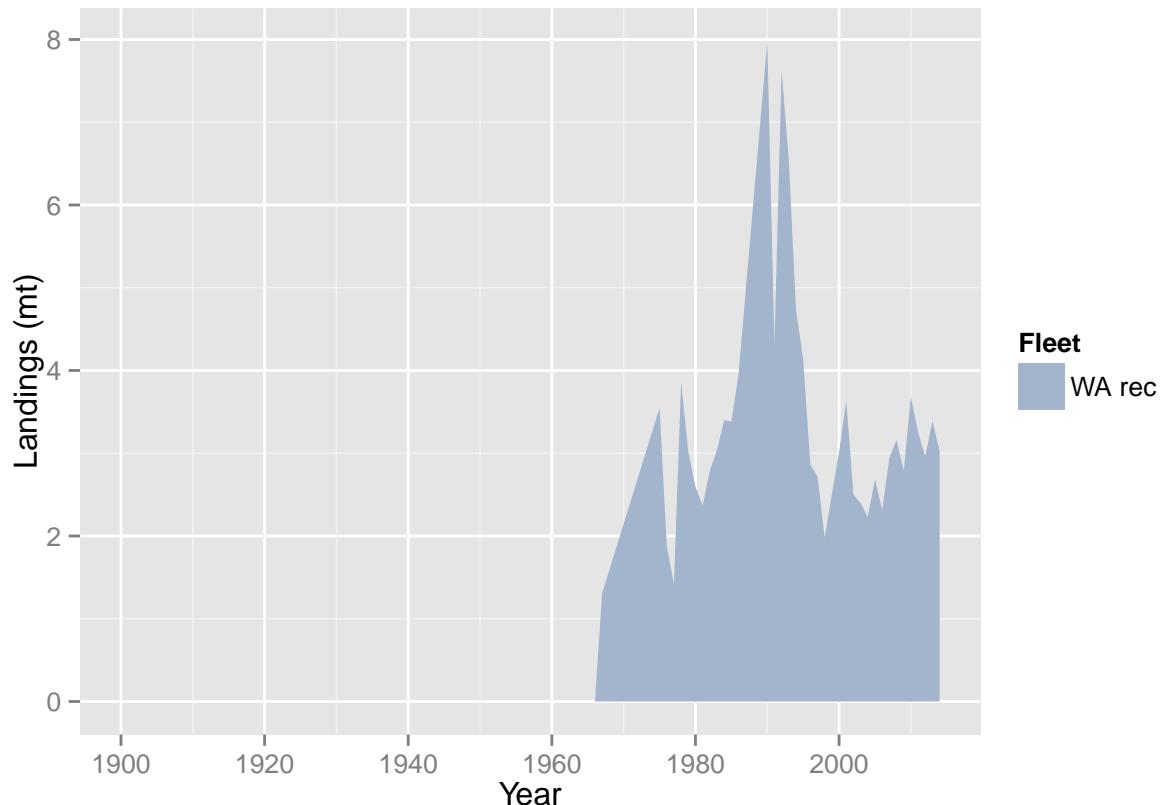

Figure a: China rockfish landings for Washington. Washington has does not have a commercial nearshore fishery.

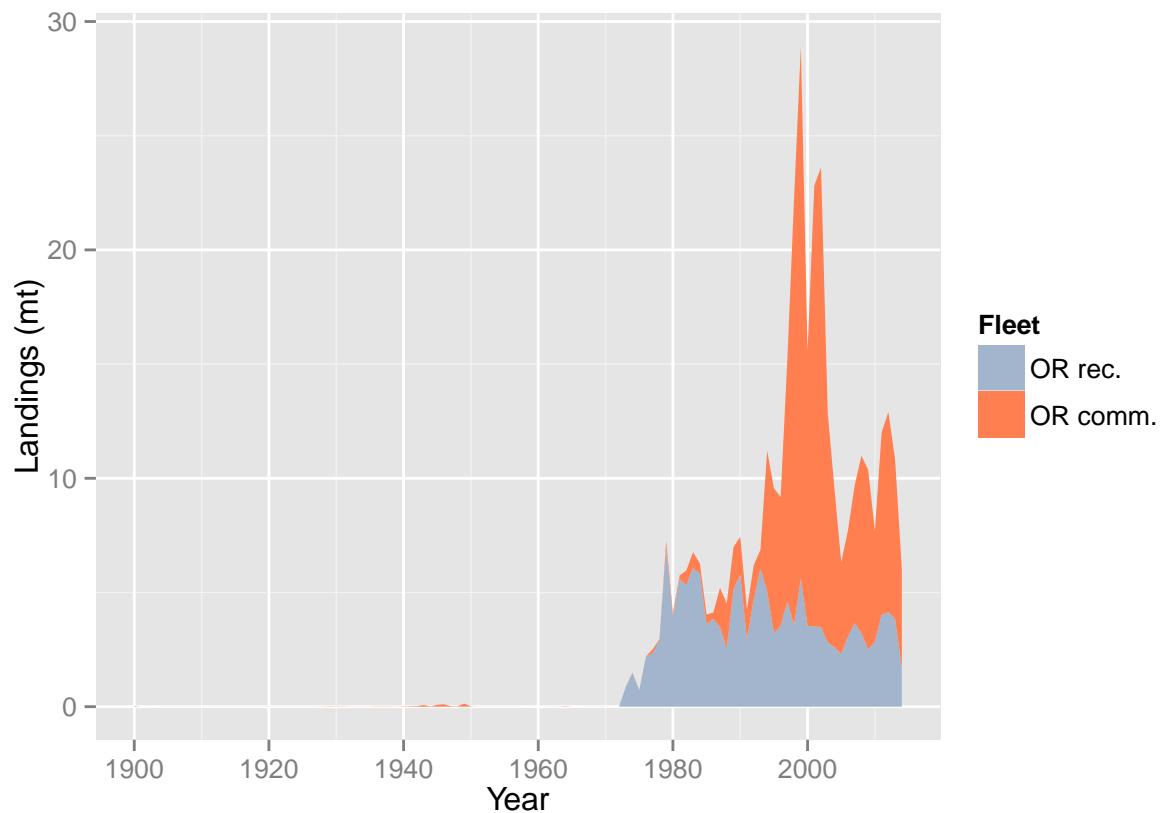

Figure b: Stacked line plot of China rockfish landings history for Oregon by fleet (recreational and commercial).

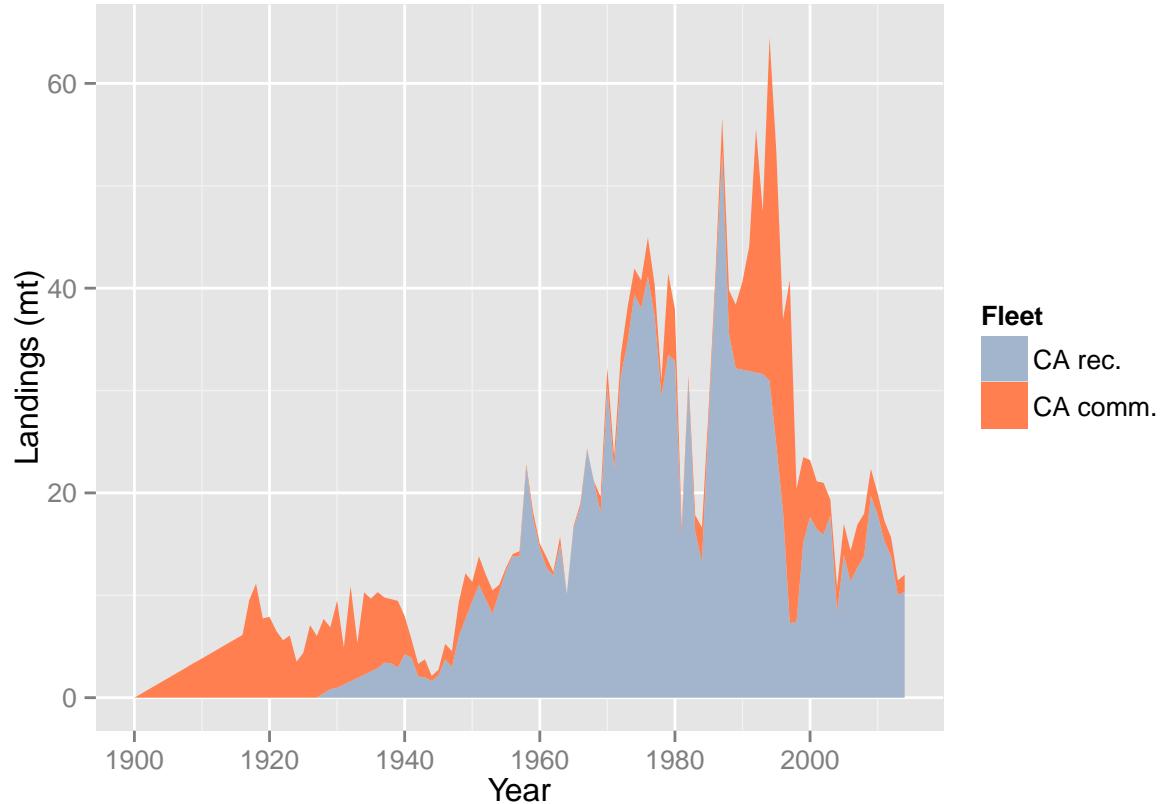

Figure c: Stacked line plot of China rockfish landings history for California by fleet (recreational and commercial).

Table a: Recent China rockfish landings (mt) by fleet.

Year	Washington recreational	Oregon commercial	Oregon recreational	California commercial	California recreational	Total
2005	2.69	4.02	2.31	3.06	13.91	25.98
2006	2.31	4.64	3.07	3.00	11.35	24.37
2007	2.94	6.03	3.66	4.21	12.70	29.54
2008	3.16	7.76	3.22	4.15	13.82	32.12
2009	2.79	7.88	2.50	2.63	19.72	35.52
2010	3.68	4.84	2.85	2.11	17.85	31.34
2011	3.26	7.98	4.02	1.99	15.29	32.54
2012	2.96	8.76	4.14	1.83	13.80	31.49
2013	3.39	6.98	3.85	1.43	10.03	25.68
2014	3.03	4.38	1.67	1.69	10.32	21.08

## 148 Data and assessment

149 China rockfish was assessed as a data moderate stock in 2013 (Cope et al. 2015) using the  
 150 XDB-SRA modeling framework. This assessment uses the newest version of Stock Synthesis  
 151 (3.24u). The model begins in 1900, and assumes the stock was at an unfished equilibrium  
 152 that year.

153 Data within the central and northern models were stratified as follows: central model north  
 154 and south of Florence, OR and the northern model groups MCAs 1-2 (southern WA) and  
 155 MCAs 3-4 (northern WA) (Figure d). Data for the management area south of 40°10' N.  
 156 latitude are aggregated, in part because historical removals from the dominant fisheries  
 157 (recreational charter and private boat modes) prior to 2004 are not available at a finer spatial  
 158 scale. The data used in the assessments includes commercial and recreational landings,  
 159 Catch per Unit Effort (CPUE) indices from recreational and commercial fleets, and length  
 160 and age compositions. Discard data (total discards in mt and size compositions) from the  
 161 commercial live-fish fishery were modelled south of 40°10' N. latitude. Where available,  
 162 age and length compositions for the recreational party/charter (CPFV) and private/rental  
 163 modes were developed separately.

## 164 Stock biomass

165 Estimated spawning output in the northern area (Washington state) declined between the  
 166 1960s and 1990s but has been largely stable during the past two decades (Figure e and Table  
 167 b). The estimated relative depletion level (spawning output relative to unfished spawning  
 168 output) of the northern stock in 2015 is 73.4% (~95% asymptotic interval: ± 63.6% - 83.2%)  
 169 (Figure f).

170 The central area model for China rockfish estimates that spawning output is just above

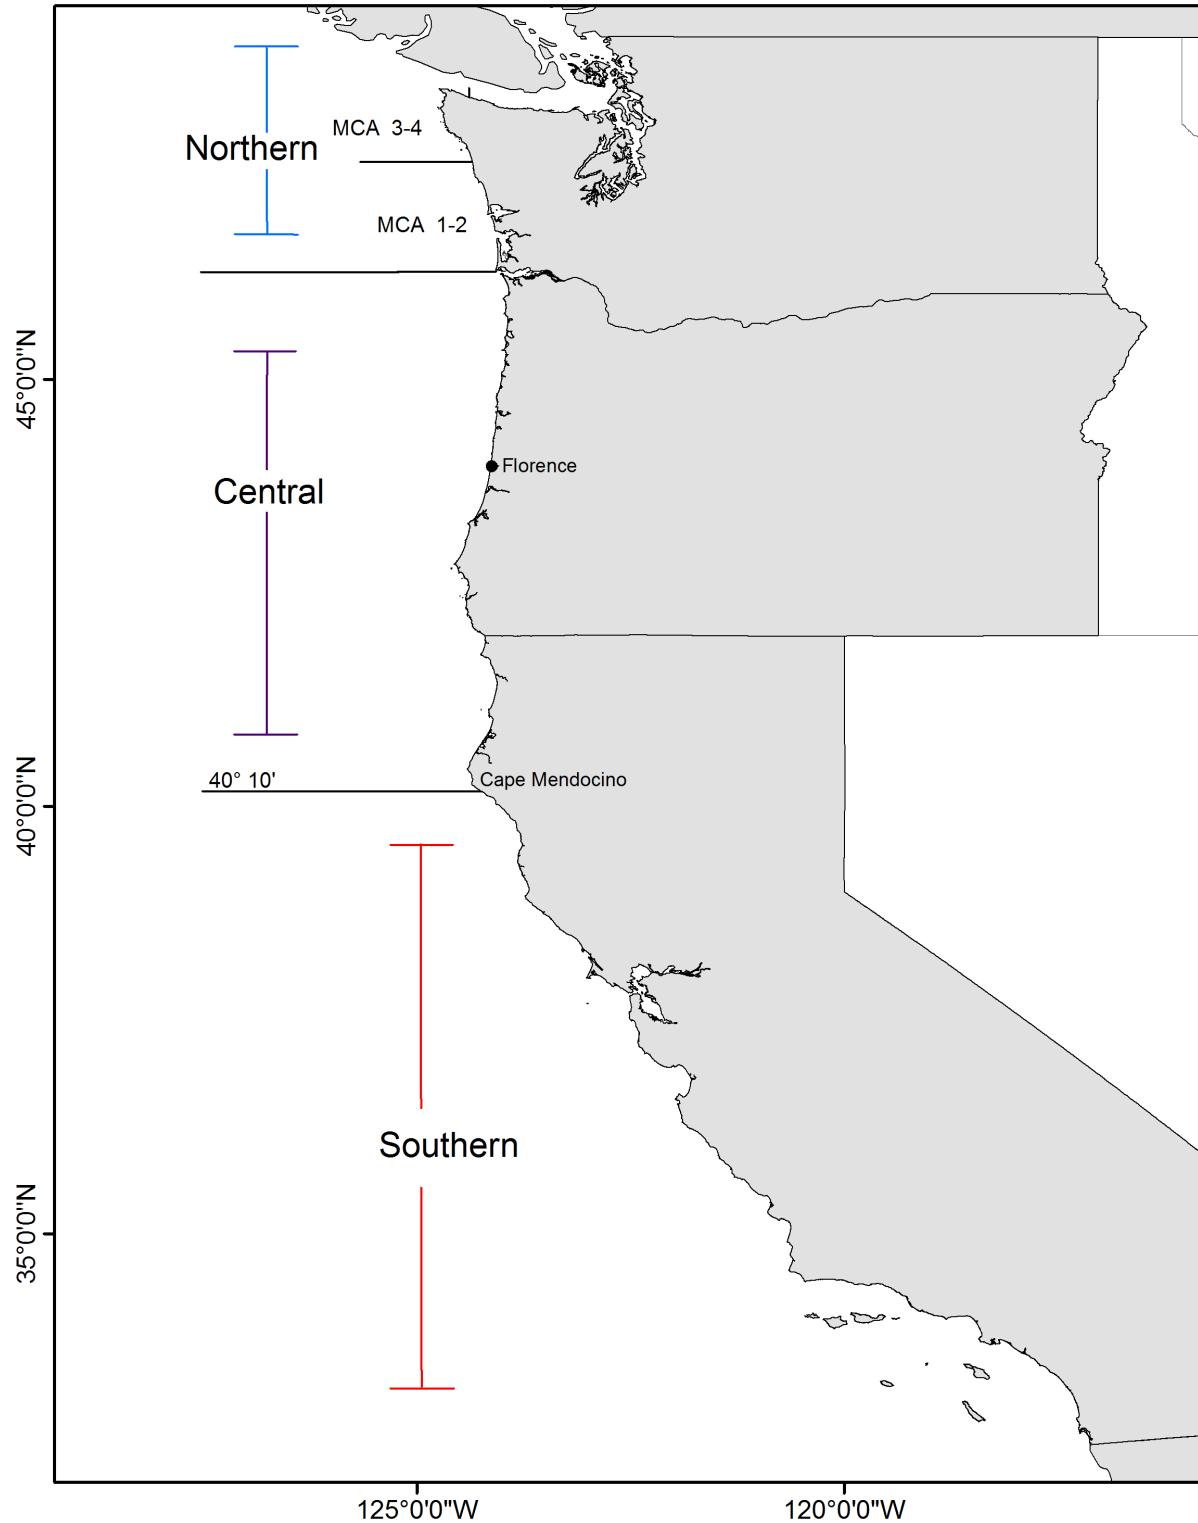

Figure d: Map depicting the boundaries for the three base-case models, Southern model (south of  $40^{\circ}10'$  N. latitude), Central model (south of  $40^{\circ}10'$  N. latitude to the OR-WA border), and the Northern model (WA state MCAs 1-4).

<sup>171</sup> the biomass target in 2015 (Figure [e](#) and Table [c](#)). The rate of spawning output decline is  
<sup>172</sup> estimated to be steepest during the 1980s to 1990s and continued to decline from the early  
<sup>173</sup> 2000s at a slower rate to an estimated minimum of 39.6% in 2014. The estimated relative  
<sup>174</sup> depletion level of the central stock in 2015 is 61.5% (~95% asymptotic interval:  $\pm 53.8\%$  -  
<sup>175</sup> 69.2%) (Figure [f](#)).

<sup>176</sup> The assessment for the southern management area suggests that China rockfish were lightly,  
<sup>177</sup> but steadily exploited since the early 1900s, with more rapid declines in spawning output  
<sup>178</sup> beginning with development of the recreational fishery in the 1950s (Figure [e](#) and Table  
<sup>179</sup> [d](#)). The estimated relative depletion level of the southern stock in 2015 is 29.6% (~95%  
<sup>180</sup> asymptotic interval:  $\pm 25.0\%$  - 34.3%) (Figure [f](#)). Although spawning output in the southern  
<sup>181</sup> area is more depleted than the central and northern areas, it is the only area with an  
<sup>182</sup> increasing trend over the past 15 years.

Table b: Recent trend in beginning of the year biomass and depletion for the northern China rockfish model.

Year	Spawning Output (billion eggs)	~ 95% confidence interval	Estimated depletion	~ 95% confidence interval
2006	17.942	(8.86-27.03)	0.734	(0.638-0.83)
2007	18.030	(8.94-27.12)	0.738	(0.642-0.833)
2008	18.044	(8.95-27.14)	0.738	(0.643-0.833)
2009	18.034	(8.93-27.13)	0.738	(0.642-0.833)

2015	40.033	(26.88-53.19)	0.615	(0.538-0.692)

Table d: Recent trend in beginning of the year spawning output and depletion for the southern (south of  $40^{\circ}10'$  N. latitude) China rockfish model.

Year	Spawning Output (billion eggs)	$\sim 95\%$ confidence interval	Estimated depletion	$\sim 95\%$ confidence interval
2006	14.430	(9.47-19.39)	0.217	(0.164-0.27)
2007	15.173	(10.01-20.34)	0.228	(0.174-0.283)
2008	15.819	(10.46-21.18)	0.238	(0.182-0.294)
2009	16.289	(10.77-21.81)	0.245	(0.187-0.303)
2010	16.361	(10.75-21.97)	0.246	(0.186-0.306)
2011	16.444	(10.73-22.16)	0.247	(0.186-0.309)
2012	16.758	(10.91-22.6)	0.252	(0.189-0.315)
2013	17.168	(11.18-23.15)	0.258	(0.193-0.323)
2014	17.899	(11.73-24.07)	0.269	(0.203-0.336)
2015	18.565	(12.23-24.9)	0.279	(0.211-0.347)

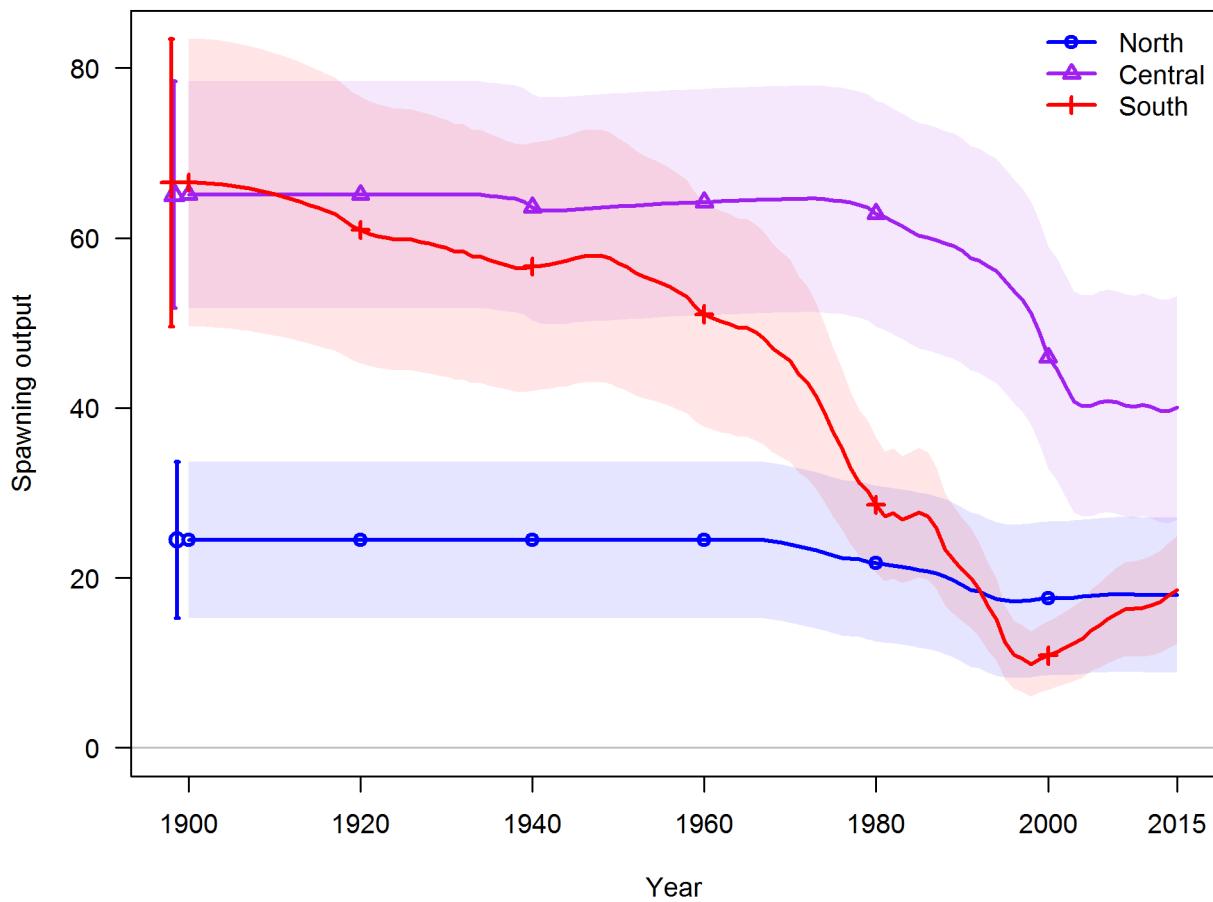

Figure e: Time series of spawning output trajectory (circles and line: median; light broken lines: 95% credibility intervals) for the three models of China rockfish (North=Washington state, Central =  $40^{\circ}10'$  N. latitude to the OR/WA border, and South = south of  $40^{\circ}10'$  N. latitude).

Figure f: Estimated relative depletion with approximate 95% asymptotic confidence intervals (dashed lines) for the three base case assessment models.

<sup>183</sup> **Recruitment**

<sup>184</sup> Length and age composition data for China rockfish contain insufficient information to reli-  
<sup>185</sup> ably resolve year-class strength. Therefore, all three base models assume that recruitment  
<sup>186</sup> follows a deterministic Beverton-Holt stock-recruitment relationship, so trends in recruit-  
<sup>187</sup> ment reflect trends in estimated spawning output. Given the assumed value of steepness and  
<sup>188</sup> estimates of current stock status, estimated recruitment has remained fairly constant in the  
<sup>189</sup> central and northern models, while the estimated biomass in the southern area has declined  
<sup>190</sup> enough to impact spawning output (Figure g, Tables e, f and g).

Table e: Recent recruitment for the northern model (Washington state MCAs 1-4).

Year	Estimated Recruitment (1,000s)	~ 95% confidence interval
2006	33.29	(21.33 - 45.24)
2007	33.30	(21.35 - 45.25)
2008	33.30	(21.35 - 45.26)
2009	33.30	(21.35 - 45.26)
2010	33.31	(21.35 - 45.26)
2011	33.30	(21.34 - 45.25)
2012	33.29	(21.33 - 45.25)
2013	33.29	(21.33 - 45.25)
2014	33.29	(21.33 - 45.25)
2015	33.29	(21.33 - 45.25)

Table f: Recent recruitment for the central model (40°10' N. latitude to the OR/WA border).

Year	Estimated Recruitment (1,000s)	~ 95% confidence interval
2006	68.27	(54.59 - 81.94)
2007	68.31	(54.64 - 81.97)
2008	68.26	(54.59 - 81.94)
2009	68.20	(54.51 - 81.9)
2010	68.17	(54.47 - 81.87)
2011	68.22	(54.52 - 81.91)
2012	68.17	(54.46 - 81.87)
2013	68.09	(54.36 - 81.81)
2014	68.06	(54.32 - 81.8)
2015	68.15	(54.43 - 81.87)

Table g: Recent recruitment for the southern model (south of  $40^{\circ}10'$  N. latitude).

Year	Estimated Recruitment (1,000s)	$\sim 95\%$ confidence interval
2006	122.32	(105.92 - 138.73)
2007	123.93	(107.67 - 140.18)
2008	125.23	(109.07 - 141.39)
2009	126.13	(109.98 - 142.28)
2010	126.27	(109.96 - 142.57)
2011	126.42	(109.97 - 142.87)
2012	126.99	(110.52 - 143.46)
2013	127.71	(111.29 - 144.13)
2014	128.94	(112.72 - 145.15)
2015	129.99	(113.95 - 146.03)

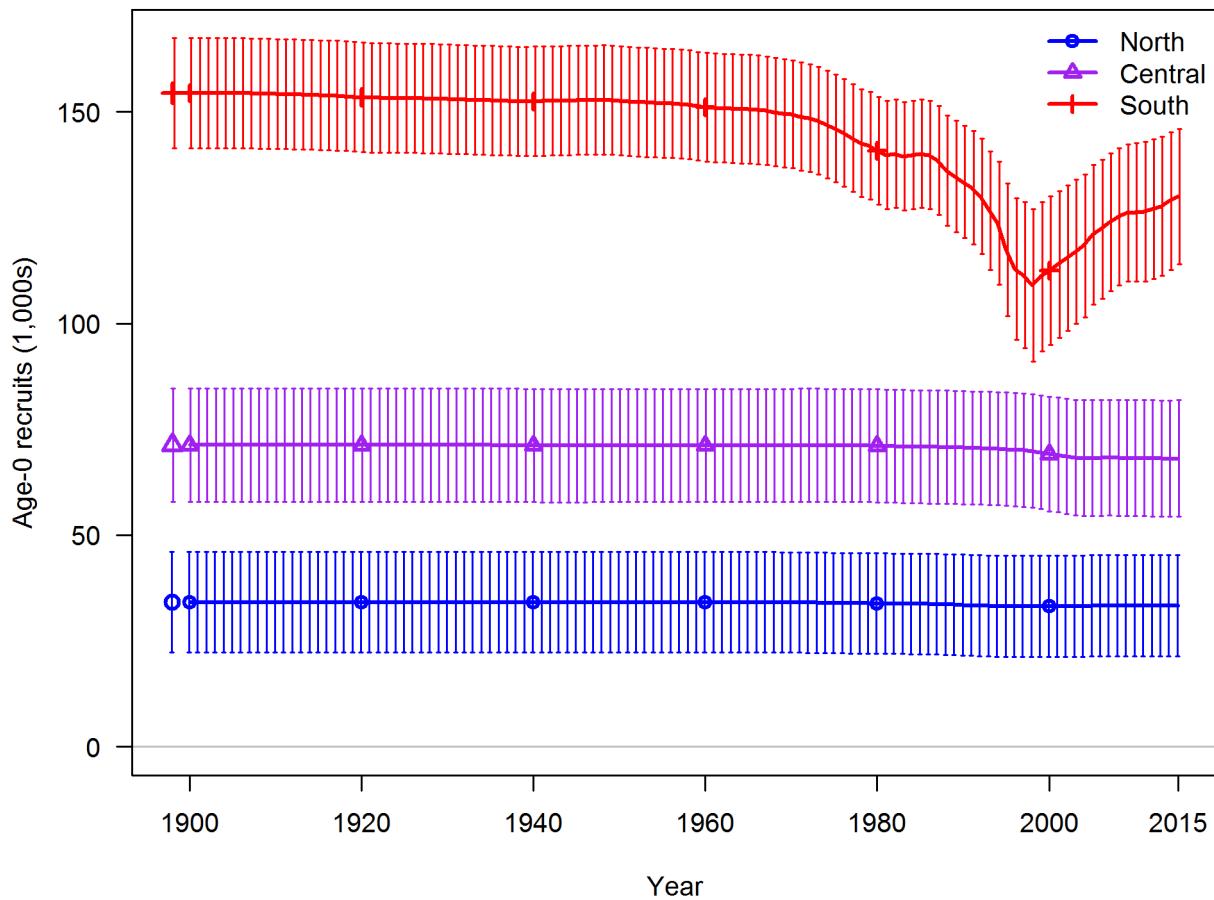

Figure g: Time series of estimated China rockfish recruitments for the three base-case models with 95% confidence or credibility intervals.

<sup>191</sup> **Exploitation status**

<sup>192</sup> Harvest rates estimated by the northern area model for Washington have never exceeded  
<sup>193</sup> management target levels (Table [h](#) and Figure [h](#)). Model results for the central area suggest  
<sup>194</sup> that harvest rates have briefly exceeded the current proxy MSY value around 2000, but has  
<sup>195</sup> remained below the management target in the last decade (Table [i](#) and Figure [h](#)). Historical  
<sup>196</sup> harvest rates for China rockfish rose steadily in the southern management area until the  
<sup>197</sup> mid-1990s and exceeded the target SPR harvest rate for several decades, and is just below  
<sup>198</sup> the target harvest rate as of 2013 (Table [j](#) and Figure [h](#)). A summary of China rockfish  
<sup>199</sup> exploitation histories for the northern, central, and southern areas is provided as Figure [i](#).

Table h: Recent trend in spawning potential ratio and exploitation for the northern China rockfish model (Washington state MCAs 1-4). Fishing intensity is (1-SPR) divided by 50% (the SPR target) and exploitation is F divided by  $F_{SPR}$ .

Year	Fishing intensity	~ 95% confidence interval	Exploitation rate	~ 95% confidence interval
2005	0.44	(0.27-0.61)	0.32	(0.17-0.47)
2006	0.39	(0.24-0.55)	0.28	(0.15-0.4)
2007	0.47	(0.3-0.65)	0.35	(0.19-0.51)
2008	0.50	(0.32-0.68)	0.38	(0.2-0.55)
2009	0.45	(0.28-0.63)	0.33	(0.18-0.49)
2010	0.56	(0.36-0.76)	0.44	(0.24-0.64)
2011	0.51	(0.32-0.7)	0.39	(0.21-0.57)
2012	0.48	(0.3-0.66)	0.35	(0.19-0.52)
2013	0.53	(0.34-0.72)	0.41	(0.22-0.59)
2014	0.48	(0.3-0.67)	0.36	(0.19-0.53)

Table i: Recent trend in spawning potential ratio and exploitation for the central China rockfish model ( $40^{\circ}10'$  N. latitude to the OR/WA border). Fishing intensity is  $(1-SPR)$  divided by 50% (the SPR target) and exploitation is  $F$  divided by  $F_{SPR}$ .

Year	Fishing intensity	$\sim 95\%$ confidence interval	Exploitation rate	$\sim 95\%$ confidence interval
2005	0.55	(0.42-0.68)	0.40	(0.28-0.52)
2006	0.62	(0.49-0.76)	0.48	(0.34-0.62)
2007	0.78	(0.63-0.93)	0.68	(0.48-0.88)
2008	0.82	(0.66-0.97)	0.73	(0.52-0.95)
2009	0.78	(0.63-0.93)	0.68	(0.48-0.88)
2010	0.61	(0.48-0.75)	0.47	(0.33-0.61)
2011	0.80	(0.65-0.96)	0.72	(0.5-0.93)
2012	0.85	(0.69-1.01)	0.79	(0.55-1.02)
2013	0.77	(0.62-0.93)	0.67	(0.47-0.87)
2014	0.53	(0.4-0.66)	0.39	(0.27-0.5)

Table j: Recent trend in spawning potential ratio and exploitation for the southern China rockfish model (south of  $40^{\circ}10'$  N. latitude). Fishing intensity is  $(1-SPR)$  divided by 50% (the SPR target) and exploitation is  $F$  divided by  $F_{SPR}$ .

Year	Fishing intensity	$\sim 95\%$ confidence interval	Exploitation rate	$\sim 95\%$ confidence interval
2005	1.30	(1.16-1.45)	1.50	(1.15-1.85)
2006	1.18	(1.03-1.33)	1.19	(0.91-1.47)
2007	1.18	(1.03-1.33)	1.22	(0.93-1.51)
2008	1.23	(1.08-1.37)	1.35	(1.04-1.67)
2009	1.35	(1.21-1.48)	1.76	(1.34-2.17)
2010	1.34	(1.2-1.48)	1.70	(1.29-2.1)
2011	1.25	(1.1-1.4)	1.41	(1.06-1.75)
2012	1.20	(1.05-1.35)	1.27	(0.96-1.58)
2013	1.02	(0.86-1.18)	0.90	(0.68-1.12)
2014	1.04	(0.89-1.2)	0.96	(0.73-1.19)

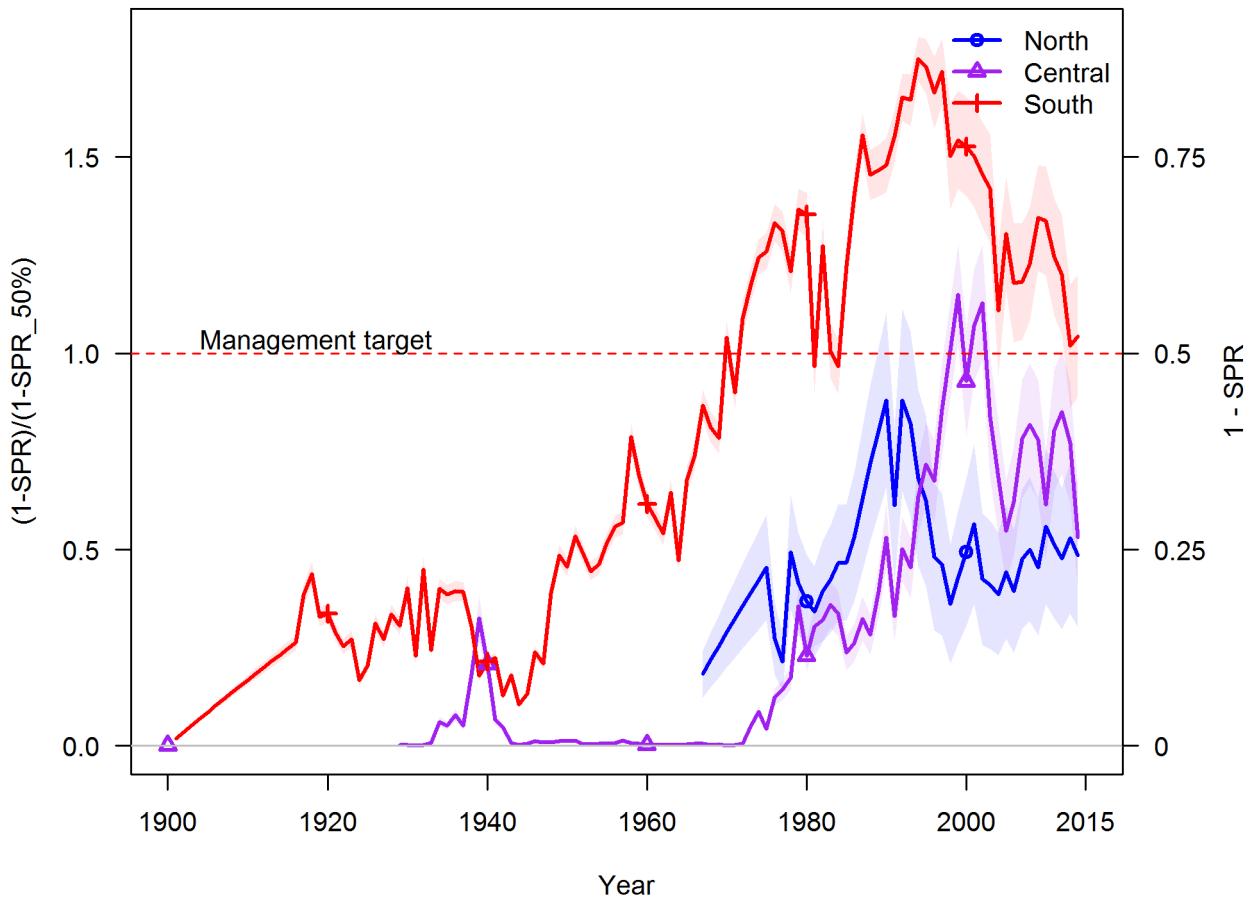

Figure h: Estimated spawning potential ratio (SPR) for the northern, central, and southern base-case models. One minus SPR is plotted so that higher exploitation rates occur on the upper portion of the y-axis. The management target is plotted as a red horizontal line and values above this reflect harvests in excess of the overfishing proxy based on the SPR<sub>50%</sub> harvest rate. The last year in the time series is 2014.

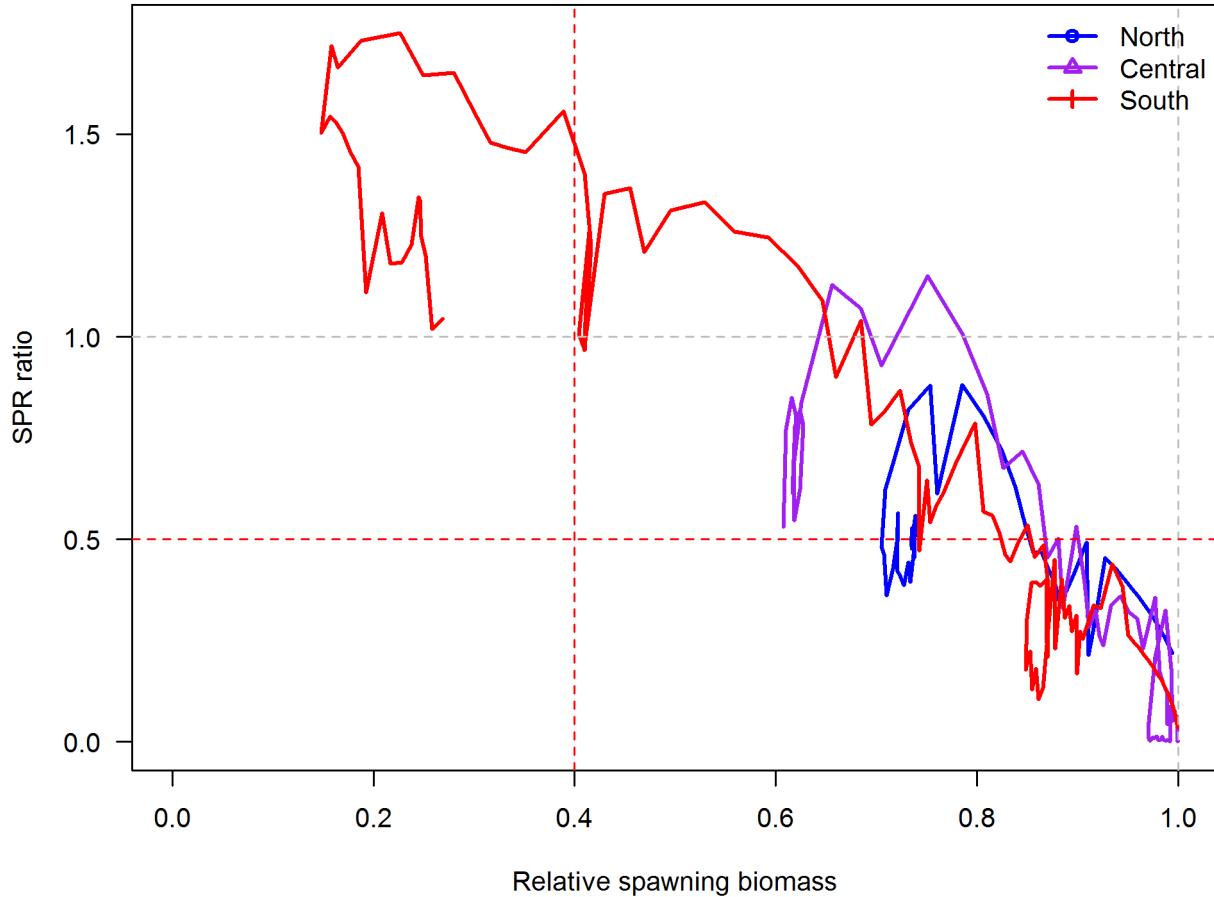

Figure i: Phase plot of estimated relative (1-SPR) vs. relative spawning biomass for the southern, central, and northern base case models. The relative (1-SPR) is (1-SPR) divided by 50% (the SPR target). Relative depletion is the annual spawning biomass divided by the unfished spawning biomass.

200 **Ecosystem considerations**

- 201 In this assessment, ecosystem considerations were not explicitly included in the analysis.  
202 This is primarily due to a lack of relevant data and results of analyses (conducted elsewhere)  
203 that could contribute ecosystem-related quantitative information for the assessment.  
204 Recently available habitat information was used to select the data used in the onboard  
205 observer indices (see Appendix F, p.9).

206 **Reference points**

- 207 The management line for China rockfish is at 40°10' N. latitude, with differing management  
208 guidelines north and south. From 2005-2010, the Nearshore Rockfish Complexes north and  
209 south of 40°10' N. latitude were managed by a total catch Optimum Yield (OY). As of the  
210 Pacific Fishery Management Council (PFMC) 2011-12 management cycle, China rockfish  
211 has a component OFL and ABC within the northern and southern Nearshore Rockfish  
212 Complexes, based on the work by Dick and MacCall (2010).  
213 This stock assessment estimates that China rockfish in the north are above the biomass  
214 target. The spawning output of the stock declined between the 1960s and 1990s but has  
215 largely been stable during the past few decades. The estimated relative depletion level in  
216 2015 is 73.4% (~95% asymptotic interval:  $\pm 63.7\% - 83.2\%$ , corresponding to an unfished  
217 spawning output of 24.4 billion eggs (~95% asymptotic interval: 15.2 – 33.7 billion eggs) of  
218 spawning output in the base model (Table k). Unfished age 5+ biomass was estimated to be  
219 240.8 mt in the base case model. The target spawning output based on the biomass target  
220 ( $SB_{40\%}$ ) is 9.8 billion eggs, which gives a catch of 6.3 mt. Equilibrium yield at the proxy  
221  $F_{MSY}$  harvest rate corresponding to  $SPR_{50\%}$  is 5.8 mt.  
222 This stock assessment estimates that central area China rockfish are just above the biomass  
223 target. The rate of spawning output decline is estimated to be steepest during the 1980s to  
224 1990s and has continued to decline since the 1990s at a slower rate. The estimated relative  
225 depletion level in 2015 is 61.5% (~95% asymptotic interval:  $\pm 53.8\% - 69.2\%$ ), corresponding  
226 to an unfished spawning output of 65.1 billion eggs (~95% asymptotic interval: 51.8 – 78.4  
227 billion eggs) of spawning output in the base model (Table l). Unfished age 5+ biomass was  
228 estimated to be 591.5 mt in the base case model. The target spawning output based on the  
229 biomass target ( $SB_{40\%}$ ) is 26 billion eggs, which gives a catch of 15.7 mt. Equilibrium yield  
230 at the proxy  $F_{MSY}$  harvest rate corresponding to  $SPR_{50\%}$  is 14.5 mt.  
231 This stock assessment estimates that China rockfish south of 40°10' N. latitude are below the  
232 biomass target, but above the minimum stock size threshold, and have been increasing over  
233 the last 15 years. The estimated relative depletion level in 2015 is 27.9% (~95% asymptotic  
234 interval:  $\pm 21.2\% - 34.7\%$ ), corresponding to an unfished spawning output of 66.5 billion eggs  
235 (~95% asymptotic interval: 49.6 - 83.4 billion eggs) of spawning output in the base model  
236 (Table m). Unfished age 5+ biomass was estimated to be 768.6 mt in the base case model.

<sup>237</sup> The target spawning output based on the biomass target ( $SB_{40\%}$ ) is 26.6 billion eggs, which  
<sup>238</sup> gives a catch of 21.1 mt. Equilibrium yield at the proxy  $F_{MSY}$  harvest rate corresponding  
<sup>239</sup> to  $SPR_{50\%}$  is 19.5 mt.

Table k: Summary of reference points and management quantities for the northern (Washington state MCAs 1-4) base case model.

Quantity	Estimate	95% Confidence Interval

## 240 Management performance

241 China rockfish is managed in the northern and southern Nearshore Rockfish Complex (split at  
 242 40°10' N. latitude. Since the 2011-2012 management cycle, China rockfish has a contribution  
 243 OFL and ACL within each the northern and southern Nearshore Rockfish Complexes (Table  
 244 n). The estimated catch of China rockfish north of 40°10' N. latitude of Nearshore Rockfish  
 245 Complex has been above both the China rockfish contribution to the northern Nearshore  
 246 Rockfish Complex OFL and ACL in all years (2011-2014). The estimated catch of China  
 247 rockfish south of 40°10' N. latitude of Nearshore Rockfish Complex has been below the China  
 248 rockfish contribution to the northern Nearshore Rockfish Complex OFL and ACL in all years  
 249 (2011-2014). A summary of these values as well as other base case summary results can be  
 250 found in Table s.

Table n: Recent trend in total catch and commercial landings (mt) relative to the management guidelines. Estimated total catch reflect the commercial landings plus the model estimated discarded biomass. Note: 2015 and 2016 ACLs are proposed and not yet in regulations

Year	Management guideline	Nearshore rockfish north	China contrib. north	Estimated catch north	Nearshore rockfish south	China contrib. south	Estimated catch south

**251 Unresolved problems and major uncertainties**

**252** As in most/all stock assessments, the appropriate value for stock-recruit steepness remains  
**253** a major uncertainty for China rockfish. In this assessment a prior value was available from  
**254** a meta-analysis, allowing bracketing of the uncertainty. Exploration of the southern model  
**255** during the STAR panel meeting established that the range of uncertainty in current and  
**256** projected biomass status provided by this bracketing was very similar to the range due to  
**257** natural mortality, and that natural mortality alone would be used to bracket uncertainty in  
**258** model results for management advice.

**262** While the northern and the southern area models are able to estimate a plausible value of  
**263** natural mortality with an apparently good level of precision, this was not possible with the  
**264** central area model.

**262** The fishery-dependent abundance indices used in the assessment are relatively noisy. There  
**263** is no fishery-independent index. The assessments assume that trends in CPUE indices are  
**264** representative of population trends.

**265** Assessment results for the central and the northern area models are dependent on the method  
**266** used for weighting the conditional age-at-length data. This is an area of active research and  
**267** there is a lack of consensus on an agreed approach. A workshop is planned for later this year  
**268** that might provide guidance. For this assessment, the Panel recommended use of harmonic  
**269** mean method, because it is a well-understood and frequently applied method that provided  
**270** intermediate results compared to other alternatives.

**271** The current term of reference for stock assessment require development of a single decision  
**272** table with states of nature ranging along the dominant axis of uncertainty. This presumes  
**273** that uncertainty is consequential only for a single variable or estimated quantity, such as  
**274** natural mortality, steepness, or ending biomass. This approach may fail to capture important  
**275** elements of uncertainty that should be communicated to the Council and its advisory bodies.  
**276** Additional flexibility in the development of decision tables is needed.

**277 Decision Tables**

**278** The forecasts of stock abundance and yield were developed using the final base models. The  
**279** total catches in 2015 and 2016 are set to the PFMC adopted China rockfish contribution  
**280** ACLs in the northern and central models (Table [n](#)). The southern model total catches in  
**281** 2015 and 2016 are set to the average annual catch from 2012-2014. The exploitation rate  
**282** for 2017 and beyond is based upon an SPR harvest rate of 50%. The average of 2010-2014  
**283** catch by fleet was used to distribute catches in forecasted years. The forecasted projections  
**284** of the OFL for each model are presented in Table [o](#).

**285** Uncertainty in the forecasts is based upon the three states of nature agreed upon at the STAR  
**286** panel and are based on a low value of M, 0.05, and a high value, 0.09. Current medium-term  
**287** forecasts based on the alternative states of nature project that the stock, under the current

control rule as applied to the base model, will decline towards the target stock size Table p. The current control rule under the low state of nature results in a stock decline into the precautionary zone, while the high state of nature maintains the stock at near unfished levels. Removing the catches resulting from the low M state of nature, assuming the base and high values of M both maintain the stock at well above the current target stock size, as does removing the recent average catches under all states of nature. Removing the high M catches under the base model M and high M states of nature results in the population going to extremely low levels during the projection period, spawning biomass and stock depletion values are not reported for years in which the stock goes to these very low levels.

Current medium-term forecasts based on the alternative states of nature for the central model project that the stock, under the current control rule as applied to the base model, will decline towards the target stock size Table q. The current control rule under the low state of nature results in a stock in the precautionary zone, while the high state of nature maintains the stock increasing from 40% to 50% depletion from 2017 - 2026. Removing the catches resulting from the low M state of nature, assuming the base and high values of M both maintain the stock at well above the current target stock size. Removing the high M catches under the base model M and low M states of nature results in the population going to extremely low levels during the projection period. Removing average catches under the base M and high M states of nature result in the stock remaining above the current target stock size, and an ending depletion of 37% in 2026 for the low M state of nature.

Assuming that catches in 2015 and 2016 equal recent average catch, and that catches beginning in 2017 follow the default ACL harvest control rule, projections of expected China spawning output from the southern base model suggest the stock will be at roughly 30% of unfished spawning output in 2017, and increase to 38% by 2026 (Table r). The stock is expected to remain below the target stock size (40% of unfished spawning output) in the base model and “low M” states of nature through 2026, and to exceed target size in the “high M” scenario, assuming stationarity in the stock-recruitment assumptions.

Table o: Projections of potential OFL (mt) for each model, using the base model forecast.

Year	North	Central	South	Total
2017	9.63	20.52	13.31	43.46
2018	9.29	20.05	13.84	43.18
2019	8.98	19.62	14.34	42.93
2020	8.69	19.21	14.80	42.71
2021	8.43	18.84	15.24	42.51
2022	8.20	18.50	15.63	42.33
2023	7.99	18.19	16.00	42.18
2024	7.80	17.91	16.34	42.05
2025	7.64	17.67	16.65	41.95
2026	7.49	17.45	16.93	41.87

Table p: Summary of 10-year projections beginning in 2017 for alternate states of nature based on an axis of uncertainty for the northern model. Columns range over low, mid, and high states of nature, and rows range over different assumptions of catch levels.

		States of nature						
		Low M 0.05		Base M 0.07		High M 0.09		
	Year	Catch	Spawning Output	Depletion	Spawning Output	Depletion	Spawning Output	
40-10 Rule, Low M	2017	3.39	10.1	0.541	18.2	0.745	59.30	0.93
	2018	3.37	10.1	0.541	18.1	0.741	59.30	0.93

Figure j: Equilibrium yield curve for the base case models. Values are based on the 2014 fishery selectivity and with steepness fixed at 0.773.

315 **Research and data needs**

316 We recommend the following research be conducted before the next assessment:

- 317 1. The number of hours fished in Washington should be recorded for each dockside sample  
318 (vessel) so that future CPUE can be measured as angler hours rather than just number  
319 of anglers per trip. This will allow for a more accurate calculation of effort.
- 320 2. The number of hours fished in Oregon should be recorded for each dockside sample  
321 (vessel), instead of the start and end times of the entire trip. This will allow for a more  
322 accurate calculation of effort.
- 323 3. Compare the habitat-based methods used to subset data for the onboard observer  
324 indices to Stephens-MacCall and other filtering methods.
- 325 4. Explore the sensitivity of Stephens-MacCall when the target species is “rare” or not  
326 common encountered in the data samples.
- 327 5. A standardized fishery independent survey sampling nearshore rockfish in all three  
328 states would provide a more reliable index of abundance than the indices developed  
329 from catch rates in recreational and commercial fisheries. However, information value  
330 of such surveys would depend on the consistency in methods over time and space and  
331 would require many years of sampling before an informative index could be obtained.
- 332 6. A coastwide evaluation of genetic structure of China rockfish is a research priority.  
333 Genetic samples should be collected at sites spaced regularly along the coast throughout  
334 the range of the species to estimate genetic differences at multiple spatial scales (i.e.,  
335 isolation by distance).
- 336 7. Difficulties were encountered when attempting to reconstruct historical recreational  
337 catches at smaller spatial scales, and in distinguishing between landings from the pri-  
338 vate and charter vessels. Improved methods are needed to allocate reconstructed recre-  
339 ational catches to sub-state regions within each fishing mode.
- 340 8. There was insufficient time during the STAR Panel review to fully review the abun-  
341 dance indices used in the China rockfish assessments. Consideration should be given to  
342 scheduling a data workshop prior to STAR Panel review for review of assessment input  
343 data and standardization procedures for indices, potentially for all species scheduled  
344 for assessment. The nearshore data workshop, held earlier this year, was a step in this  
345 direction, but that meeting did not deal with the modeling part of index development.
- 346 9. The Marine Recreational Fisheries Statistics Survey (MRFSS) index in Oregon was  
347 excluded from the assessment model because it was learned that multiple intercept  
348 interviews were done for a single trip. Evaluate whether database manipulations or  
349 some other approach can resolve this issue and allow these data to be used in the  
350 assessment.

- 351 10. Many of the indices used in the China rockfish assessment model used the Stephens-  
352 MacCall (2004) approach to subset the CPUE data. Research is need to evaluate  
353 the performance of the method when there are changes in management restrictions  
354 and in relative abundance of different species. Examination of the characteristics of  
355 trips retained/removed should be a routine part of index standardization, such as an  
356 evaluation of whether there are time trends in the proportion of discarded trips.
- 357 11. Fishery-dependent CPUE indices are likely to be the only trend information for many  
358 nearshore species for the foreseeable future. Indices from a multi-species hook-and-line  
359 fishery may be influenced by regulatory changes, such as bag limits, and by interactions  
360 with other species (e.g., black rockfish) due to hook competition. It may be possible  
361 to address many of these concerns if a multi-species approach is used to develop the  
362 indices, allowing potential interactions and common forcing to be evaluated.
- 363 12. Consider the development of a fishery-independent survey for nearshore stocks. As  
364 the current base model structure has no direct fishery-independent measure of stock  
365 trends, any work to commence collection of such a measure for nearshore rockfish, or  
366 use of existing data to derive such an index would greatly assist with this assessment.
- 367 13. Basic life history research may help to resolve assessment uncertainties regarding ap-  
368 propriate values for natural mortality and steepness.
- 369 14. Examine length composition data of discarded fish from recreational onboard observer  
370 programs in California and Oregon. Consider modeling discarded catch using selec-  
371 tivity and retention functions in Stock Synthesis rather than combining retained and  
372 discarded catch and assuming they have identical size compositions. Another option  
373 would be to model discarded recreational catch as a separate fleet, similar to the way  
374 commercial discards were treated in the southern model.
- 375 15. Ageing data were influential in the China rockfish stock assessments. Collection and  
376 ageing of China rockfish otoliths should continue. Samples from younger fish not  
377 typically selected by the fishery are needed to better define the growth curve.
- 378 16. Consider evaluating depletion estimators of abundance using within season CPUE  
379 indices. This approach would require information on total removals on a reef-by-reef  
380 basis.
- 381 17. The extensive use of habitat information in index development is a strength of the  
382 China rockfish assessment. Consideration should be given to how to further incorporate  
383 habitat data into the assessment of nearshore species. The most immediate need seems  
384 to be to increase the resolution of habitat maps for waters off Oregon and Washington,  
385 and standardization of habitat data format among states.
- 386 18. Although all the current models for China rockfish estimated implausibly large recruit-  
387 ment deviations when allowed to do so, particularly early in the modeled time period,

388 further exploration of available options in stock synthesis could produce acceptable re-  
389 sults. In addition, this work may provide guidance on any additional options that could  
390 be added to stock synthesis to better handle this situation. For example, assuming dif-  
391 ferent levels autocorrelation in the stock-recruit relationship for data-moderate stocks  
392 may help curb the tendency to estimate extreme recruitment with sparse datasets.

393 19. Research is needed on data-weighting methods in stock assessments. In particular,  
394 a standard approach for conditional age-at-length data is needed. The Center for  
395 the Advancement of Population Assessment Methodology (CAPAM) data weighting  
396 workshop, scheduled for later this year, should make important progress on this research  
397 need.

398 **1 Introduction**

399 **1.1 Basic Information and Life History**

400 China rockfish (*Sebastes nebulosus*) is a medium-sized, commercially (mainly in the live-fish  
401 fishery) and recreationally prized deeper-dwelling nearshore rockfish ranging from southern  
402 California, north to the Gulf of Alaska (Love et al. 2002). Core abundance is found from  
403 northern California to southern British Columbia, Canada. China rockfish are rarely encoun-  
404 tered in the Southern California Bight (Love et al. 1998).

405 There is limited information available on either stock structure or life history. No genetic  
406 research has been conducted for China rockfish, and no published research indicates separate  
407 stocks along the West Coast. China rockfish do not appear to exhibit sexual dimorphism  
408 (Lenarz and Echeverria 1991), although data are limited. Fits to von Bertalanffy growth  
409 curves (Bertalanffy 1938) using age-length data from Washington, Oregon, and California  
410 indicate regional differences in growth and estimates of  $L_{\infty}$ . These data represent fish col-  
411 lected from the recreational and commercial sectors as well as for research.

412 China rockfish are among the longer-lived rockfish. Love (2002) reports China rockfish live to  
413 at least 79 years, which is corroborated by the available age data used in this assessment. The  
414 oldest aged China rockfish from Alaska was 78 years old (Munk 2001). Recently aged China  
415 rockfish from the West Coast had a maximum age of 83 years from California (recreational  
416 or research) in 1973. The oldest aged fish from Oregon was 79 from the commercial dead-fish  
417 fishery in 2003 and in Washington, 77 years from the recreational fleet in 2000.

418 Little is known about the maturity schedule and fecundity of China rockfish. Echeverria  
419 (1987) collected 69 China rockfish, of which the age at first maturity was 3 years for males  
420 and females (26 cm). Both males and females exhibited 50% maturity at 4 years (27 cm) and  
421 100% maturity at 6 years (30 cm). A study by Lea et al. (1999) captured females releasing  
422 larvae in April and May, and spent females in April, June and October off the coast of  
423 California. Echeverria (1987) identified January - June as the months of parturition for  
424 China rockfish in north-central California, with the peak of reproductive activity in January.

425 One diet study indicated that China rockfish in central California predominantly feed on  
426 crustaceans and ophiuroids, while the diets of China rockfish in northern California was  
427 dominated by crustaceans and mollusks (Lea et al. 1999). This is similar to the diet described  
428 by Love et al. (2002) of benthic organisms, including brittle stars, crabs, and shrimps.

429 Both juvenile and adult China rockfish tend to be solitary and exhibit high site fidelity  
430 within rocky habitats. Surveys of rockfishes in *Nereocystis* and *Macrocystis* kelp forests  
431 observed China rockfish in only the *Macrocystis* kelp forests, and overall sightings within  
432 the kelp forests were rare (Bodkin 1986). Juvenile China rockfish inhabit shallow, subtidal  
433 waters (Love et al. 2002), and an experimental study with captive China rockfish found  
434 that juveniles exhibit both site fidelity and territoriality (Lee and Berejikian 2009). A tag  
435 and recapture study by Lea et al. (1999) indicated China rockfish have high site fidelity.

436 While Lea et al. (1999) did not report exact distances, all China rockfish from the study  
437 were recaptured in the same “general locality at which they were released.” In other rockfish  
438 movement studies, China rockfish were tagged but never recaptured (Hanan and Curry 2012),  
439 or there was a sample size of one fish (Hannah and Rankin 2011). An ongoing study has used  
440 acoustic telemetry to tag and track seven China rockfish at Redfish Rocks, off the south coast  
441 of Oregon (pers. comm. Tom Calvanese, Oregon State University). The location where each  
442 fish was released after tagging was recorded using GPS. The maximum distance traveled  
443 from release point was calculated using the location of the most distant receiver at which  
444 that fish was detected, plus 250 m (estimated receiver detection range). Preliminary analyses  
445 estimate the maximum distance traveled by China rockfish (n=7) averaged  $1,344 \pm 334$  m  
446 between May 1, 2011, and December 31, 2012.

447 Little is known about dispersal of juvenile China rockfish during the pelagic stage, and they  
448 are not captured in the Southwest Fisheries Science Center’s (SWFSC) juvenile rockfish  
449 cruise. The 2013 assessment model treated the species as two stocks, north and south of  
450 Cape Mendocino, CA ( $40^{\circ}10'$  N. latitude), which is also the management boundary for  
451 China rockfish. For this assessment we explore assessment models north and south of  $40^{\circ}10'$   
452 N. latitude, as well as separate northern California/Oregon and Washington models in the  
453 north.

#### 454 1.1.1 Early Life History

455 China rockfish, like other species in the genus *Sebastodes*, are iteroparous, have internal fertil-  
456 ization, and bear live young. Gestation periods range from 1-2 months among the *Sebastodes*  
457 spp. that have been studied, but no data specific to China rockfish were found in our liter-  
458 ature search. Parturition (release of larvae into the water) by China rockfish was reported  
459 between January and June in Central California (Echeverria 1987), but the duration of the  
460 pelagic larval and juvenile stages is unknown. Closely-related, nearshore rockfish species  
461 (e.g. gopher, black-and-yellow, kelp, and copper) recruit at small sizes (1.5-2 cm), and are  
462 thought to have short pelagic juvenile stages relative to other *Sebastodes* (Anderson 1983, Love  
463 et al. 2002).

#### 464 1.2 Map

465 A map showing the scope of the assessment and depicting boundaries for fisheries or data  
466 collection strata is provided in Figure 1.

#### 467 1.3 Ecosystem Considerations

468 In this assessment, ecosystem considerations were not explicitly included in the analysis.  
469 However, we did use information on the distribution of rocky habitat to inform the onboard

470 observer program indices of relative abundance from California and Oregon. The onboard  
471 observer program collects location-specific encounters of China rockfish. We overlaid the  
472 locations of China rockfish encounters with high-resolution bathymetry data to obtain a  
473 proxy of the extent of China rockfish habitat (see Appendix F for details, p.[F-1](#)).

474 Much research is needed to elucidate the role of China rockfish in the ecosystem, including  
475 predator/prey interactions.

## 476 1.4 Fishery Information and Summary of Management History

477 The rockfish fishery off the U.S. Pacific coast first developed off California in the late 19th  
478 century as a hook-and-line fishery (Love et al. 2002). The rockfish trawl fishery was es-  
479 tablished in the early 1940s, when the United States became involved in World War II and  
480 wartime shortage of red meat created an increased demand for other sources of protein (Harry  
481 and Morgan 1961, Alverson et al. 1964). China rockfish are most commonly captured by  
482 hook-and-line or traps. They are rarely encountered in the trawl fishery due to the elusive  
483 behavior and affinity for rocky crevices. Their high site fidelity and territoriality lend to the  
484 evasiveness of the species.

485 Catch reconstructions of China rockfish indicate a developing fishery in California in the  
486 1940s, and not until the 1970s in Oregon. The recreational fishery in Washington developed  
487 in the late 1960s, but the magnitude of catches compared to the other states is relatively  
488 small. China rockfish is not a directed target recreational species in any of the three states.

489 Prior to 2000, the Pacific Fishery Management Council (PFMC; Council) managed the  
490 fishery for China rockfish as part of the *Sebastes* complex, with no separate Acceptable  
491 Biological Catch (ABC) or Optimum Yield (OY) for China rockfish. In 2000, the Council  
492 established the northern and southern Nearshore Complexes (north and south of 40°10' N.  
493 latitude), of which China rockfish is included.

494 The Council established management guidelines for the northern and southern Nearshore  
495 Rockfish Complexes in the 2005-2006 management cycle (Total Catch OY; 122 mt north of  
496 40°10' N. latitude and 615 mt south of 40°10' N. latitude). The 2011-2012 management cycle  
497 adopted and Overfishing Limit (OFL) and Annual Catch Limit (ACL) for the northern and  
498 southern Nearshore Rockfish Complexes, and the China rockfish contribution to the complex,  
499 which differ north and south of 40°10' N. latitude. In 2003, the Council established Rockfish  
500 Conservation Areas to control catches of overfished rockfish species, and large portions of  
501 the shelf were closed to fishing.

502 In 1995, Washington closed commercial hook-and-line gear in state waters (0-3 miles). Ore-  
503 gon's commercial nearshore fishery developed in the mid 1990s as an open access fishery.  
504 Oregon adopted formal management of the commercial nearshore fishery in 2004. Oregon  
505 adopted a 12 inch size limit in the commercial fishery for China rockfish in 2000, and Cali-  
506 fornia did the same in 2001. California required a nearshore fishery permit as of 1999 and

507 has had area-specific closures since 2000 to minimize interactions with canary and yelloweye  
508 rockfishes.

509 Washington adopted depth closures for the recreational fishery in 2006 for MCAs 2 (closed  
510 seaward of 30 fm), 3 (closed seaward of 20 fm) and 4 (closed seaward of 20 fm).

511 In November 2002, Oregon implemented the first depth closure seaward of 27 fm. In general,  
512 from June 1 - September 30, groundfish are prohibited seaward of 40 fm from 2004-2009.  
513 In July 2010 and 2011, seaward of 20 fm was closed due to yelloweye rockfish interactions.  
514 From 2012-2014, groundfish take seaward of 30 fm from April 1-September 30 is prohibited.  
515 As of 2015, retention of China rockfish is prohibited in the Oregon recreational fishery.

516 California adopted a 3-hook and 1-line regulation in 2000, which changed to 2-hooks and  
517 1-line in 2001. California manages the recreational fishery through management areas, which  
518 have been dynamic through time. In general starting in 2004, north of 40°10' N. latitude to  
519 the CA/OR border, the nearshore rockfish fishery is closed seaward of 30 fm May-December,  
520 (and closed in January-April as of 2005). In 2008, the depths seaward of 20 fm were  
521 closed May-August and the closures from September-December change annually through  
522 2014. Depth closures between Pt. Conception and Cape Mendocino have been much more  
523 dynamic. In general, depth closures began in 2001 at 20 fm and have dynamically varied by  
524 month and depth (20-40 fm) through 2014.

## 525 1.5 Management Performance

526 China rockfish is managed in the northern and southern Nearshore Rockfish Complex, split at  
527 40°10' N. latitude. Since the 2011-2012 management cycle, China rockfish has a contribution  
528 OFL and ACL within each the northern and southern Nearshore Rockfish Complexes (Table  
529 n). The estimated catch of China rockfish north of 40°10' N. latitude of Nearshore Rockfish  
530 Complex has been above both the China rockfish contribution to the northern Nearshore  
531 Rockfish Complex OFL and ACL in all years (2011-2014). The estimated catch of China  
532 rockfish south of 40°10' N. latitude of Nearshore Rockfish Complex has been below the China  
533 rockfish contribution to the northern Nearshore Rockfish Complex OFL and ACL in all years  
534 (2011-2014). A summary of these values as well as other base case summary results can be  
535 found in Table s.

## 536 2 Assessment

### 537 2.1 Data

538 Data used in the China rockfish assessment are summarized in Figures 2 - 4. A description  
539 of each data source is below.

540 **2.1.1 Fishery-Dependent Data: Commercial Landings**

541 **Washington**

542 Washington does not have a nearshore commercial fishery and there are no records of China  
543 rockfish being landed by any commercial gears in Washington. There is no record of tribal  
544 catch of China rockfish in Washington.

545 **Oregon**

546 China rockfish landings from Oregon commercial fisheries were minor until twenty years  
547 ago (Table 1, Figure 5). Prior to the mid-1990s, there were only trace landings of China  
548 rockfish from longline fisheries (i.e., less than one metric ton per year), and no landings  
549 from the trawl fisheries (based on species composition samples obtained since the 1960s)  
550 (Douglas 1998). However, landings of China rockfish rapidly increased from 1995-2000 due  
551 to the emergence of a live-fish market that paid high prices for ornate rockfish, such as  
552 China rockfish (especially in Southern Oregon). Following a peak in catch from 1998-2000,  
553 decreased landings of China rockfish during the early 2000s coincided with new regulations  
554 designed to limit harvests from the live fish fishery, such as landings limits, permit limits,  
555 and minimum size limits (Rodomsky et al. 2014).

556 There is a relatively high degree of confidence in the accuracy of historic China rockfish  
557 landings because comprehensive sampling of commercial landings began before the fishery  
558 for China rockfish developed. Specifically, since 1992, the Oregon Department of Fish and  
559 Wildlife has obtained robust species composition samples from landings categories containing  
560 China rockfish at fine levels of stratification (i.e., year, quarter, gear, disposition, area caught,  
561 and market category). China rockfish landed into improper market categories, has been  
562 practically non-existent, presumably due to the high price differential for China rockfish (as  
563 opposed to other rockfish). China rockfish landings since 1992 were obtained from PacFIN,  
564 which estimates species specific landings of rockfish by the above mentioned strata.

565 However, China rockfish landings could not be obtained from PacFIN prior to 1992 since  
566 China rockfish were not included in species composition samples (of rockfish category land-  
567 ings) from the longline and rod-and-reel fisheries (and thus China rockfish landings incor-  
568 rectly appear as zeros in PacFIN). Accordingly, landings of China rockfish were obtained  
569 from the commercial catch reconstruction developed by Karnowski et al. (2014), whom  
570 borrowed species compositions (from earliest complete years) and applied them to market  
571 category landings from years before species compositions were obtained.

572 All China rockfish landings from the Karnowski et al. (2014) reconstruction were used except  
573 for those occurring from the salmon troll fishery, which were reported as 1-2 metric tons per  
574 year from the mid-1960s to the early 1990s. Since a species composition had never been  
575 obtained from the market categories containing China rockfish for the salmon troll fishery,  
576 Karnowski et al. (2014) borrowed species compositions from the recreational salmon fishery  
577 and applied them to the commercial salmon troll fishery landings. Although China rockfish  
578 appeared in the recreational salmon fishery landings, it was concluded at the Nearshore

579 Stock Assessment Workshop ([Agenda Item D.8 Attachment 10](#), June 2015) that the China  
580 rockfish caught during recreational salmon trips were not caught by troll gear, but rather by  
581 jig gear from anglers who also targeted benthic rockfish species before or after trolling for  
582 salmon. Since China rockfish are associated with rocky reef habitat (Love et al. 1998) and  
583 salmon trollers fish the surface waters for coho salmon and avoid rocky reefs when fishing  
584 for Chinook salmon (to prevent entanglement of expensive downrigger gear on rocks), it was  
585 deemed improbable that China rockfish be caught by salmon troll gear.

## 586 California

587 The [CALCOM](#) database was queried (May 15, 2015) for commercial landing estimates of  
588 China rockfish in California, 1969-2014. Landings were stratified by year, quarter, live/dead,  
589 market category, gear group, port complex, and source of species composition data (actual  
590 port samples, borrowed samples, or assumed nominal market category).

591 The majority of commercial China rockfish landings are made by vessels using hook-and-  
592 line gear ([Figure 6](#)). However, CALCOM landings estimates also include a large fraction of  
593 trawl-caught China rockfish from 1969-1988, which is unlikely given the species' preference  
594 for rocky habitat. The reported trawl catch was mainly from the Monterey port complex  
595 and was landed in the "China rockfish" market category (258).

596 An analysis of species composition data from port samples in market category 258, by  
597 gear type, revealed that the sampled trawl-caught landings contained mainly deeper-water  
598 species, including greenspotted rockfish (*Sebastodes chlorostictus*), sometimes known as "chin-  
599 na fish." Species landed by hook-and-line gears in the China rockfish market category, on  
600 the other hand, consisted of a mixture of nearshore species (e.g., China, quillback, gopher,  
601 black-and-yellow, and brown; [Figure 7](#)). When port samples are not available to estimate  
602 species composition in a stratum, and no samples are available to 'borrow' from an adjacent  
603 stratum, landings in a market category are assigned to the 'nominal' species category, in  
604 this case China rockfish.

605 Given the available species composition data from the trawl catch, and the fact that trawl  
606 gear is unlikely to be fished in China rockfish habitat, estimates of trawl-caught China  
607 rockfish were removed from the landings estimates in the current assessment. A similar  
608 analysis led to the removal of a small amount (about 5 mt) of landings by set-net and  
609 mid-water trawl gear groups.

610 In years prior to 1978, landing receipts are available for California but there are no associated  
611 port sample data. In CALCOM, a ratio estimator (based on the expanded landings estimates  
612 in the earliest sampled years) is used to allocate catch to species in unsampled years. In  
613 the case of China rockfish, this procedure propagated the estimates of trawl-caught China  
614 backward in time to 1969 ([Figure 6](#)). These ratio estimates of trawl-caught China rockfish  
615 were also removed from the final time series of landed catch.

616 The previous assessment of China rockfish (Cope et al. 2015) modeled two China rockfish  
617 populations, north and south of 40°10' N. latitude (roughly Cape Mendocino). The majority

618 of landings occurred south of Cape Mendocino, and the revised estimates are substantially  
619 lower in early years, primarily due to the removal of trawl catch (Figure 8).

620 California's commercial live-fish fishery began targeting nearshore rockfish species in the mid-  
621 1980s in southern California, and condition codes (live or dead) were required on landing  
622 receipts starting in 1993 (CDFG 2002). However, fish landed live are not always recorded  
623 as live landings on the landing receipts, so estimates of live landings should be viewed as a  
624 minimum estimate (CDFG 2002). Live annual landings of China rockfish surpassed landings  
625 of dead fish by the late 1990s, due to the increased value of fish landed live (Table 2, Figure  
626 9).

627 Commercial landings of China rockfish in California from 1916-1968 were obtained from  
628 the historical reconstruction of Ralston et al.(2010), and also available from the CALCOM  
629 website. Their analysis differentiates between trawl-caught landings and “other” gears. In  
630 the case of China rockfish, less than 2 mt of landings from 1916-1968 were attributed to  
631 trawl gears, and these were excluded from the assessment. The remaining “other” gear types  
632 (cumulative removals of 197 mt from 1916-1968) landed China rockfish mainly south of Cape  
633 Mendocino, with a short pulse of landings between Cape Mendocino and the California-  
634 Oregon border in the 1930s and early 1940s (Figure 10). Due to the relatively large landing  
635 estimates south of Cape Mendocino in the early years, catches from 1900 to 1916 were  
636 interpolated with a linear ramp from 0 mt in 1900 to 6.1 mt in 1916 (the first year of  
637 commercial landings estimated by Ralston et al. (2010)).

### 638 2.1.2 Fishery-Dependent Data: Commercial Discards

#### 639 Washington

640 Discards of China rockfish likely occurred before the closure of nearshore commercial fisheries  
641 in 1995 for non-trawl gears and in 1999 for trawl gears. However, there is no information on  
642 historical discards. For this assessment, we assume no retention or discard of China in any  
643 commercial fisheries.

#### 644 Oregon and California

645 Estimates of discarded China rockfish in commercial fisheries were provided by the West  
646 Coast Groundfish Observer Program (WCGOP). These were available for the years 2003-  
647 2013 north of 40°10' N. latitude, and 2004-2013 to the south. WCGOP provided estimates  
648 with and without the depth-specific discard mortality rates applied. These estimates indicate  
649 that the nearshore fixed-gear fishery was the only sector with observed discards of China  
650 rockfish and there were strong differences in rates of discarding north and south of 40°10' N.  
651 latitude, (Figure 11 and Table 3). The mortality of discarded China rockfish is estimated  
652 by WCGOP as a function of the fishing depth which varies by year (Table 3). The average  
653 mortality fraction south of 40°10' across all years was 59%.

654 Discard rates were consistently low north of 40°10' N. latitude, where no year had estimated  
655 mortality from discards greater than either 0.5 mt, or 5% of the landings. A linear regression

656 relating discarded to retained catch (with intercept fixed at the origin) had a slope of 0.0269,  
657 indicating that discards on average represent 2.69% of the landings in this sector (Figure  
658 12). This value is similar to a simple average of the discard fractions, which was 2.75%.

659 South of 40°10' N. latitude, commercial landings were lower and estimated discards higher.  
660 The maximum discard mortality estimate was 1.8 mt for 2012 which was 126% of the 1.4 mt  
661 nearshore fixed gear landings in that area in that year. The total discard amount for that  
662 year, including fish estimated as surviving, was 2.7 mt, almost double the landed amount.  
663 There is also an increasing trend over the observed period (2004-2013) with an average for  
664 the first three years of 30% of all China rockfish catch discarded and an average over the  
665 final three years of 63% discarded.

666 Discard patterns in the area of Northern California between 40°10' N. latitude, and 42° N.  
667 latitude appears to be more similar to Oregon than the rest of California (Table 4). Although  
668 expanded fleet-wide discard estimates were not available on this smaller spatial-scale, only  
669 9% of observed trips between 40°10' N. latitude to 42° N. latitude that were associated with  
670 any catch of China rockfish had any observed discards of China rockfish. South of 40°10',  
671 82%-100% of such trips had observed discards of China rockfish.

672 The patterns of the discards in commercial fisheries suggest that north of 40°10' N. latitude  
673 discard mortality of China rockfish is small enough that it is more parsimonious to account for  
674 this mortality increasing the landed catch estimates by 2.69%. South of 40°10' N. latitude,  
675 total discards are greater than landings in some years and discard mortality represents a  
676 large fraction of the total mortality of China rockfish. The discards are primarily fish below  
677 the minimum legal size of 12 inches (Figure 64). The discard process was modelled using  
678 a retention function in the pre-STAR panel base model, but this approach did not capture  
679 the increasing trend in discard rates, which may be an indication of changes in population  
680 size structure that should be accounted for in the assessment. The final southern base  
681 model treated discarded catch as a separate fleet, exactly matching removals that were dead  
682 discarded catch, and fitting length composition data from WCGOP in the model.

### 683 2.1.3 Fishery-Dependent Data: Recreational Landings and Discards

#### 684 Washington

685 Historically, Washington's coastal recreational anglers have been salmon-orientated and most  
686 groundfish were considered "scrap fish" by anglers (Buckley 1967). Beginning in the mid-  
687 1970s, and particularly in the wake of the 1974 Boldt Decision, salmon fishing opportunities  
688 became increasingly restrictive; seasons were shortened and daily limits were reduced. The  
689 trend continued into the 1980s and 1990s. In 1994, and for the first time in the state's history,  
690 a one year moratorium on all ocean salmon fishing was implemented in response to dwindling  
691 salmon runs. As salmon fishing opportunities waned over time, recreational and commercial  
692 fishers began shifting their interests to other species. Many recreational coastal anglers  
693 shifted their efforts to rockfish. Prior to declines in salmon fishing opportunities, rockfish,

694 though rarely discarded, were generally not targeted. The increased interest in rockfish and  
695 other groundfish can be linked directly to the decline in salmon fishing opportunities.

696 The coastal recreational fleet is composed of two sectors; privately owned vessels and charter  
697 vessels. Throughout the history of coastal charter boat fishing, Westport has remained the  
698 center of charter boat activity; however, as the salmon fishing industry declined, the charter  
699 fleet dispersed in search of more lucrative opportunities. Many of the vessels left the state,  
700 and some moved north where rockfish fishing was perceived as being more reliable. Even so,  
701 there are still more charter vessels operating at Westport than at Neah Bay and La Push.

702 The primary focus of coastal rockfish anglers is black rockfish. Black rockfish occur in  
703 greater abundance and closer to shore than other coastal rockfish species, and while generally  
704 regarded as a “bottom fish,” they tend not to occupy crack and crevice habitat, thus making  
705 them more susceptible to hook-and-line fishing. As rockfish daily limits decreased, the  
706 likelihood of recreational anglers retaining smaller rockfish species, such as China, as part of  
707 their daily bag limit likely also decreased.

708 China rockfish are more common in northern Washington coast (Marine Catch Areas (MCAs)  
709 3 and 4) from south of Tatoosh Island to Pt. Grenville inside of 15 fm and are rarely  
710 encountered south of the Point Grenville. Makah Bay and the Umatilla reef areas seem  
711 to have the largest populations in the area (Tom Burlingame, Excel Fishing Charters, pers  
712 comm). China rockfish are rare off of the central Washington coast (MCA 2) from the  
713 mouth of the Queets River to Leadbetter Point. Some chartered vessels from Westport have  
714 gone multiple seasons without encountering any China rockfish in MCA 2 (Mark Cedergreen,  
715 Westport Charterboat Association, pers comm). Suitable habitat is limited in MCA 1, from  
716 the mouth of the Leadbetter Point to the mouth of Columbia River.

717 Historical estimates of China rockfish catch during 1967 and 1975-1989 were based on his-  
718 torical sport catch report series published by Washington Department of Fisheries (Table  
719 5, Figure 14). Catches for 1968-1974 and 1987-1989 were based on a linear interpolations  
720 between adjacent years. From 1990 to current, catch estimates were produced by the Wash-  
721 ington Department of Fish and Wildlife (WDFW) Ocean Sampling Program based on a  
722 catch expansion procedure that includes a complete count of vessels leaving or entering a  
723 port and dockside angler interviews. The dockside interview program collects information  
724 on number of anglers fished, catch area, and target species. Shorebased fishing, other than  
725 major jetties, is not sampled and is considered negligible. Sampling and effort counts occur  
726 mainly from April to October. Winter fishing is also considered negligible.

727 We assumed an average weight of 0.88 kg/fish ([RecFIN](#)) to convert the estimates from number  
728 of fish to metric tons for all years. The split between charter and private vessels prior to  
729 1990 was based on a ratio estimator using 1990-1994 data.

730 More than 90% of China rockfish were caught off the northern Washington coast on an annual  
731 basis (Table 5) and the catch by private vessels accounted for 70%-95% of the northern  
732 catches. In the southern area, harvest of China has been under 0.5 mt annually; and most  
733 of China rockfish were caught by charter vessels (Table 5, Figure 14).

734 Release information was not available until 2002. Number of released fish by species and the  
735 depth of release were added to OSP dockside questionnaire in 2002 and 2005, respectively.  
736 The number of released fish by depth is estimated using the same catch expansion algorithm  
737 for retained catch. Surface release mortalities adopted by the Groundfish Management Team  
738 (GMT) were then applied to the number of release estimates for a total mortality calculation.  
739 The average weight of 0.88 kg/fish was also used for released fish. For pre-2002 release, we  
740 applied proportions of released fish based on a ratio estimator using 2003-2007 data. For  
741 the split between charter and private vessels, the same algorithm used for splitting retained  
742 catch was applied.

743 Discard rates are higher in northern Washington than in southern Washington. Since 2011,  
744 more than 50% of the China rockfish caught were released by anglers. The release rates are  
745 lower in the southern area between 14% and 26% in recent years. This may be due to the rare  
746 encountering of China off southern Washington coast.

#### 747 Oregon Sport Fishery Removals 1973-2014

748 China rockfish have been a relatively minor contributor to historic Oregon sport groundfish  
749 landings (i.e., typically less than one percent of total catch), and have primarily been from  
750 incidental catches of anglers targeting intermixed schools of midwater rockfish species (e.g.,  
751 black rockfish, blue rockfish, and yellowtail rockfish). China rockfish removals from the  
752 Oregon sport fishery ramped up relatively quickly during the 1970s (Table 6, Figure 15),  
753 and have since ranged between two and seven metric tons every year, with considerable  
754 inter-annual variation.

755 Total removals of China rockfish from the Oregon sport fisheries were obtained from esti-  
756 mates produced by the Oregon Recreational Boat Survey (ORBS). To produce total catch  
757 estimates, ORBS applies catch rates from a subsample of vessels (from dockside interviews)  
758 to total effort counts at fine levels of stratification (i.e., by week, port, fishery, and type of  
759 boat). For estimates of landings, catch rates are verified by biologists; however, estimates of  
760 discard mortality are based on angler-reported discards, and are further stratified by depth-  
761 dependent mortality rates associated with barotrauma. Since nearly all mortality of China  
762 rockfish has been from landed catch (i.e., typically less than 0.1 mt of estimated discard  
763 mortality per year), there is relatively high degree of certainty in sport fishery removals.

764 Since 2001, ORBS has produced comprehensive year-round estimates of catch and effort  
765 for all developed Oregon ports (and are available from RecFIN). However, prior to 2001,  
766 ORBS sampling was typically only conducted at major ports during the peak months of  
767 sport fishing activity, and no estimates of catch were made for unsampled ports and times.  
768 Accordingly, the Oregon Department of Fish and Wildlife (ODFW) reconstructed historic  
769 ORBS estimates of China rockfish to include catches from all ports and times (not yet  
770 available on RecFIN), as is done in recent years.

771 The sport reconstruction addressed four spatial and temporal coverage biases identified dur-  
772 ing an external review of ORBS by the RecFIN Statistical Subcommittee (Van Voorhees et  
773 al. 2000): (1) “major ports” that were sampled each year were not sampled during the win-

ter months; (2) “minor ports” were not sampled at all during some years; (3) effort counts for private boats excluded afternoon and night trips; and (4) undeveloped launch sites were never sampled (e.g., beaches). A fifth coverage bias, shoreline and estuary boat removals, was not relevant to China rockfish since landings were typically non-existent during years when sampling occurred.

The sport reconstruction utilized ratio estimators, based on years with complete sampling, to expand catches from years with partial sampling. For instance, the contribution of winter catch to total catch during years with complete sampling was used to expand catches for years with missing winter catch. Similarly, the contribution of catch from a minor port to that of the major ports during years with complete sampling was used to expand catches of years that the minor port was not sampled.

## California

In California, recreational fishing has accounted for over 70% of cumulative China rockfish removals statewide (1900-2014, landings and discard), and over 84% of statewide removals since 2005 (Table 7 and Figure 16). Almost all the removals are attributed to boat fishing modes (party/charter and private/rental fleets), with only a negligible contribution from shore-based fishing modes (RecFIN, 2015).

Estimates from the California Recreational Fisheries Survey (CRFS) were downloaded from the Recreational Fisheries Information Network ([RecFIN](#)). This survey covers the years 2004-2014, and estimates of retained plus discarded catch (catch types A and B1) were downloaded in numbers of fish as well as metric tons by year, boat mode (“PC” = party/charter, “PR”=private/rental), month, and CRFS district. In some strata, estimates of catch in numbers had no corresponding catch in weight due to missing average weight values in RecFIN. For these strata, catch in weight was estimated using the product of catch in numbers and average weight in the same year. Catches in weight (mt) were aggregated by year, boat mode, and CRFS district. As an approximation, removals in CRFS District 6 were assigned to the management area north of Cape Mendocino.

From 1980-2003, sampling of recreational fisheries in California was conducted as part of the Marine Recreational Fisheries Statistics Survey (MRFSS). Estimates of retained and discarded catch (A+B1) in numbers of fish and weight in metric tons were downloaded from the RecFIN website. Strata with estimates of catch in numbers, but no corresponding weight, were imputed using the same approach described above for the CRFS estimates. MRFSS sampling was not conducted from 1990-1992 due to lack of funding. Also, sampling of the PC boat mode north of Point Conception did not resume until 1996. Estimates for these missing years were calculated using linear interpolation, by region and boat mode.

The MRFSS program did not provide estimates of removals stratified north and south of Cape Mendocino. However, the California Department of Fish and Wildlife (CDFW) has maintained logbook records since 1957 of total rockfish catch by CDFW statistical block (Table 7) from the PC mode (a.k.a. the Commercial Passenger Fishing Vessel or “CPFV” fleet). Following the approach used in the last China rockfish assessment (Cope et al. 2015), we calculated the ratio of total rockfish catch (all species combined) for statistical blocks

815 less than 233 (blocks north of Cape Mendocino) to total rockfish catch in the area north  
816 of Point Conception ( $34^{\circ}27'$  N. latitude) by year. The ratios were then scaled such that  
817 the percentage of catch north of Mendocino in 2003 matched the observed ratio of catch in  
818 CRFS District 6 to CRFS Districts 3-6 from 2004-2011. These adjusted ratios were applied  
819 to annual MRFSS estimates for the area north of Point Conception in order to estimate  
820 landings north and south of Cape Mendocino in the years 1980-2003.

821 Estimates of recreational removals (catch and discard) from 1928-1979 were reconstructed  
822 by Ralston et al. (2010) (Table 7). Similar to the MRFSS data, the estimates produced by  
823 Ralston et al. (2010) did not partition catch to areas north and south of Cape Mendocino,  
824 so CPFV logbook data was used to determine the fraction of removals north and south of  
825 Cape Mendocino. Adjusted annual percentages (Table 8) were applied to the reconstructed  
826 recreational catches back to 1957, and the average percentage in 1957-58 (0.74%) was applied  
827 to all previous years and assumed constant back to 1928.

#### 828 2.1.4 Fishery-Dependent Data: Oregon Commercial Logbook

829 The ODFW has required nearshore commercial fishers (both nearshore permitted vessels and  
830 open access vessels) to submit fishing logbooks since 2004. Fisher compliance is generally  
831 high, averaging around 80%, but has varied through time ranging from 65% in 2007 to  
832 95% in recent years. Although required to provide all requested information in the logbook  
833 per fishing gear set, there has been substantial variation in the quantity and quality of  
834 information reported in logbooks. Responses from submitted logbooks were entered into a  
835 central database and span the years 2004 through 2013. At the time of this assessment, 2014  
836 logbook submissions were not fully processed and thus were not available. A map showing  
837 positive reports of China rockfish can be found in Figure 17.

838 Logbook information went through several data quality filters to attain as best as possible a  
839 consistent and representative data set through time to estimate a relative abundance trend.  
840 Results from the filtration algorithm are summarized in Table 9. Of note, only logbook  
841 submissions from black and blue rockfish permitted vessels with a nearshore endorsement  
842 were included in the analysis, because these vessels consistently fish in areas where China  
843 rockfish are encountered. To minimize temporal variation in reporting errors (or nuances),  
844 only vessels that fished all 10 years (2004 to 2013) were deemed the most likely to provide  
845 consistent responses through time. Operators of endorsed vessels may have changed through  
846 time. Individual observations of catch (kg) and effort (hook hour) were at the trip level,  
847 where multi-set trips were aggregated to the trip level. ODFW sets bimonthly trip landing  
848 limits for China rockfish and these have changed through time. However, trip limits have  
849 not generally been breached in the subset of logbook data used for China rockfish, and thus  
850 there was no need to exclude subsequent trips. The final subset of logbook data included  
851 3,575 trips (14% of the full set of logbook data) from 10 vessels (Figure 20).

852 Preliminary data analyses identified levels or limits of filtering variables in order to preserve  
853 adequate sample sizes and representative trips for China rockfish. For example, gear type

854 was restricted to hook-and-line (excluding longline gear) because this method accounted for  
855 85% of all sets. The three main southernmost Oregon ports (Port Orford, Gold Beach, and  
856 Brookings) were the only locations that included a sufficient number of sets throughout the  
857 time series for nearshore endorsed vessels. Thus, this abundance index is most representative  
858 of southern Oregon nearshore waters. Fishing depth at the start of a set was restricted to  
859 within 30 fm (54.9 m), which included more than 99% of all sets by nearshore endorsed  
860 vessels, to ensure only CPUE in areas where China rockfish are commonly encountered was  
861 evaluated.

862 Covariates considered in the full model included *month*, *vessel*, *port*, *depth*, and *people* (Figure 18). All covariates were specified as categorical variables, except depth was a continuous  
863 variable. *Depth* was included to account for general differences in bathymetry and fishing  
864 depth restrictions associated primarily with limiting catch of yelloweye rockfish. *People* were  
865 included in an attempt to control for the potential oversaturation of hooks at a given fishing  
866 location and the interaction that multi-crew trips (# fishers onboard) may have on fishing  
867 efficiency. The selection of covariates included in final models were evaluated using standard  
868 information criterion for relative goodness of fit (AICc and BIC) in a backwards stepwise  
869 fashion, where a covariate remained in the model if model fit was improved relative to an  
870 otherwise identical model without the covariate.

872 CPUE was modeled using a delta-GLM approach, where the catch occurrence (binomial)  
873 component was modeled using a logit link function and the positive catch component was  
874 modeled according to a gamma distribution with a log link function. CPUE was calculated  
875 for each trip, where total catch was defined as the sum total of all reported retained catch  
876 (in weight) and released catch (numbers converted to weight by applying a median catch  
877 weight) and total effort was defined by hook-hours (number of hooks used multiplied by the  
878 number of hours fished). A lognormal distribution for the positive catch component was  
879 also evaluated, but graphical summary diagnostics of model adequacy slightly favored the  
880 gamma distribution. A delta-GLMM was also attempted to specify vessel-year interaction  
881 effects as stemming from a distribution (random effect) and to account for this added source  
882 of variation. However, the estimation procedure was unstable for the delta-GLMM approach,  
883 resulting in overinflated CVs.

884 Model selection procedures identified the covariates *vessel*, *port*, *depth* and *people* as impor-  
885 tant, and along with the categorical *year* factor of interest for the index were the variables  
886 included in both the catch occurrence and positive catch component models. Extracted,  
887 back-transformed and bias corrected estimates of the *year* effect were used for the abundance  
888 index (Table 10, Figure 19). A jackknife resampling routine was conducted to estimate the  
889 standard error (and CV) of the year effects. The relative effects of each covariate are shown  
890 in Figure 21 for the catch occurrence component and Figure 22 for the positive catch com-  
891 ponent. Standard model diagnostics show adequate fit and general consistency with GLM  
892 model assumptions for the positive catch component (Figure 23).

893 **2.1.5 Fishery-Dependent Data: Recreational Dockside Surveys**

894 **Washington**

895 The WDFW provided recreational dockside fisheries data from 1981 to 2014. These data  
896 went through several data quality filters to identify the best subset of the available data that  
897 are likely to be consistent over the time series and provide a representative relative index of  
898 abundance once standardized. Sample sizes from data filtering steps prior to implementing a  
899 delta-GLM CPUE standardization resulted in 10,248 records applying the Stephens-MacCall  
900 data filter (Stephens and MacCall 2004), 16,193 records applying the Stephens-MacCall data  
901 filter to the full data set and then retaining all of the positive records, and 54,285 without  
902 applying the Stephens-MacCall data filter (Table 11). The Stephens-MacCall method is an  
903 objective approach for identifying trip records of catch and effort data when fishing locations  
904 are unknown, based inference regarding the species composition of the catch identifying  
905 habitats where the target species is likely to occur (Stephens and MacCall 2004).

906 Since recreational fishing trips target a wide variety of species, standardization of the catch  
907 rates requires selecting trips that are likely to have fished in habitats containing China  
908 rockfish. The method of Stephens and MacCall (2004) was used to identify trips with a  
909 high probability of catching China rockfish, based on the species composition of the catch  
910 in a given trip. Prior to applying the Stephens-MacCall filter, we identified potentially  
911 informative “predictor” species, i.e., those with sufficient sample sizes and temporal coverage  
912 (at least 30 positive trips total, distributed across at least 10 years of the index) to inform  
913 the binomial model. Coefficients from the Stephens-MacCall analysis (a binomial GLM) are  
914 positive for species which co-occur with China rockfish, and negative for species that are not  
915 caught with China rockfish.

916 Covariates considered in the full model included *year*, *month*, *boat type*, *daily bag limits*,  
917 and *depth restrictions* (Figure 24). All covariates were specified as categorical variables.  
918 The stepwise selection of covariates included in the final model was evaluated using standard  
919 information criterion for relative goodness of fit (AIC). *Depth* was not included in the analysis  
920 because it was not uniformly recorded through time; depth data collection began during 2003.  
921 The covariates for *daily bag limits* and *depth restrictions* represent management changes.  
922 Summer fishing restrictions based on depth limitations were implemented during 2006 in  
923 WDFW areas 2, 3, and 4. The daily rockfish limit was 15 fish from 1961-1991, 12 fish from  
924 1992-1994, and reduced to 10 fish in 1995 (see Appendix H for the history of recreational  
925 regulations, p.H-1).

926 CPUE was modeled using a delta-GLM approach, where the catch occurrence (binomial)  
927 component was modeled using a logit link function and the positive catch component was  
928 modeled after log-transformation of the response variable, according to a normal distribution  
929 with an identity link function. Data are collected at the trip level, with the number of fish  
930 landed and the number of anglers on each vessel being recorded. The amount of time fished  
931 by each angler is not recorded. Therefore, the units for CPUE are fish landed/angler-trip. A  
932 gamma distribution for the positive catch component was also explored, but model selection

933 favored the lognormal model, although both models provided similar results.

934 Model selection procedures selected the covariates *month* and *boat type* as important for  
935 both the catch occurrence and positive catch component models for all data sets, along  
936 with the categorical year factor used for the index of abundance (Tables 12, 13 and 14). A  
937 bootstrap analysis (N=500) was used to estimate the standard errors (and CVs) of the year  
938 effects (Table 15). Standard model diagnostics show adequate fit and general consistency  
939 with GLM model assumptions for the positive catch component Figures 25, 26 and 27).

940 Due to the large number of records filtered out by the Stephens-MacCall method three sets  
941 of models were run: 1) applying the Stephens-MacCall data filter, which eliminates both  
942 zero and positive observations, 2) applying the Stephens-MacCall data filter but retaining  
943 all of the positive records, and 3) without applying the Stephens-MacCall data filter (Table  
944 11). The resulting indices of China rockfish abundance using either data set subject to  
945 the Stephens-MacCall filter are similar (Figure 28). However, the index resulting from the  
946 dataset not subject to the Stephens-MacCall filter produces similar trends compared to the  
947 Stephens-MacCall filter through the mid-2000s then declines compared to the indices using  
948 the Stephens-MacCall filter from the late 2000s to present (Table 15). The model with the  
949 Stephens-MacCall filter that retained all positive encounters was the index selected for use  
950 in the assessment model (Figure 29).

951 Additional model sensitivities that did not impact the standardized index were:

952 1. The use of only area 4 data versus using all of the data with an area covariate. A strong  
953 majority of the positive data are from area 4, only these data are used in the standardized  
954 indices.

955 2. Splitting the time series in 2002 to model CPUE from 2002 to 2014 as total catch (discarded  
956 fish were recorded beginning in 2002) rather than landed catch.

957 Producing a model for just southern areas (1 and 2) was not successful due to a lack of  
958 positive data over the time series.

#### 959 California MRFSS Dockside Charter Boat Index, South of 40°10' N. latitude

960 From 1980 to 2003 the MRFSS program sampled landings at dockside (called an “intercept”)  
961 upon termination of recreational fishing trips. The program was temporarily suspended from  
962 1990-1992 due to lack of funding, and sampling of California charter boats north of San Luis  
963 Obispo County did not resume until 1995. For purposes of this assessment, the MRFSS  
964 time series is truncated at 2003 due to regulatory changes and an increasing fraction of trips  
965 sampled by onboard observers (see “Recreational Onboard Observer Surveys”). Although  
966 the program sampled various fishing modes, only the California party and charter boat (a.k.a.  
967 “PC mode,” commercial passenger fishing vessel, or CPFV) samples are used in the present  
968 analysis due to availability of catch and effort data aggregated at the trip level. Each entry  
969 in the RecFIN Type 3 database corresponds to a single fish examined by a sampler at a  
970 particular survey site. Since only a subset of the catch may be sampled, each record also  
971 identifies the total number of that species possessed by the group of anglers being interviewed.

972 The number of anglers and the hours fished are also recorded. Unfortunately the Type 3  
973 data do not indicate which records belong to the same boating trip. Because our aim is to  
974 obtain a measure of catch per unit effort (fish per angler hour), it is necessary to separate the  
975 records into individual trips. For this reason trips must be inferred from the RecFIN data.  
976 This is a lengthy process, and is outlined in Supplemental Materials (“Identifying Trips in  
977 RecFIN”).

978 Since recreational fishing trips target a wide variety of species, standardization of the catch  
979 rates requires selecting trips that are likely to have fished in habitats containing China  
980 rockfish. The method of Stephens and MacCall (2004) was used to identify trips with a  
981 high probability of catching China rockfish, based on the species composition of the catch  
982 in a given trip. Prior to applying the Stephens-MacCall filter, we identified potentially  
983 informative “predictor” species, i.e., those with sufficient sample sizes and temporal coverage  
984 (at least 30 positive trips total, distributed across at least 10 years of the index) to inform  
985 the binomial model. Coefficients from the Stephens-MacCall analysis (a binomial GLM) are  
986 positive for species which co-occur with China rockfish, and negative for species that are not  
987 caught with China rockfish. As expected, positive indicators of China rockfish trips include  
988 several species of nearshore rockfish, and counter-indicators include several species of flatfish,  
989 salmon, and deep-water rockfish (Figure 30). One species (albacore, *Thunnus alalunga*) that  
990 met the requirement of 30 positive trips over at least 10 years never co-occurred with China  
991 rockfish. All trips catching albacore were excluded from the data set used to model CPUE.  
992 Records from 1993 and 1994 were also dropped from the index, due to poor spatial coverage  
993 (all trips were in San Luis Obispo county).

994 The percentage of trips that caught China rockfish was 13.6% prior to filtering, and 70.8% in  
995 the final, filtered data set (n=431; Table 16). The number of sampler-examined trips varies  
996 by year and county, and counties with small sample sizes were aggregated with adjacent  
997 counties into four *regions*. (Table 17). Samples from Humboldt and Del Norte counties were  
998 included with the Oregon MRFSS index.

999 CPUE (number of fish per angler hour) was modelled using a “delta-GLM” model (Lo  
1000 et al. 1992, Stefánsson 1996). Model selection using AIC supported inclusion of *year* and  
1001 *region* effects in both the binomial and lognormal components of the index (Table 18). The  
1002 addition of two-month *wave* effects (to allow for seasonal changes in CPUE) did not improve  
1003 model fit. Data in the binomial component also supported inclusion of a distance from  
1004 shore variable (*AREA\_X*). Residual-based model diagnostics for the positive component of  
1005 the index suggest the data generally met the assumptions of the GLM (Figure 31). The  
1006 resulting index is highly variable, but suggests a decline in catch rates after 1995 relative to  
1007 preceding years (Table 19; Figure 32).

1008 **California North of 40°10' and Oregon Dockside Charter Boat Indices (MRFSS  
1009 and ORBS)**

1010 For the Oregon sport fisheries, three indices of abundance were used in the pre-STAR Panel  
1011 base model: (1) catch rates from the onboard observer program, (2) catch rates from the  
1012 dockside survey component of the ORBS, and (3) catch rates from the dockside MRFSS (see

1013 description of California MRFSS index, above). For the onboard observer index, all data  
1014 elements were verified by a biologist, and thus there was a high degree of certainty in the  
1015 catch, effort, and locations fished; however, there was limited spatial-temporal coverage and  
1016 only charter boats were included (not private boats). In contrast, the ORBS dockside survey  
1017 has more comprehensive coverage and much greater samples sizes (i.e., 50-70 times more trips  
1018 than onboard observer program), but there was less confidence in the data elements, as only  
1019 catch and the number of anglers were verified by biologists (all other trip details were angler-  
1020 reported). The two dockside programs (ORBS and MRFSS) differ in terms of the measure  
1021 of fishing effort (details below). A single fishing trip can be sampled in both by the onboard  
1022 observer program and also dockside within ORBS. Because the onboard observer program  
1023 data is at a much finer scale than the trip-based dockside data; we removed trips from the  
1024 ORBS database that were double-sampled and chose to retain all onboard observer trips.

1025 **Index Standardization: MRFSS Dockside Charter Boat CPUE for California**  
1026 **North of 40°10' and Oregon**

1027 An index based on MRFSS data for northern California and Oregon was developed for the  
1028 pre-STAR base model. Prior to the review meeting, it was discovered that the data were not  
1029 trip-level data, and the index was removed from the final base model, with negligible effect  
1030 on model results. The STAT recommends that future China rockfish assessments examine  
1031 trip-level MRFSS catch and effort data as a potential index of abundance.

1032 **Index Standardization: Oregon Recreational Boat Survey (ORBS) Dockside**  
1033 **Charter Boat CPUE**

1034 In order to provide estimates of total catch and effort for the Oregon sport fisheries, ORBS  
1035 obtains catch rates from a portion of vessels via a dockside survey, and applies them to total  
1036 effort counts. During the dockside survey, biologists intercept vessels returning from fishing  
1037 trips and record catch, effort, and other trip-related details (e.g., grid area fished, target  
1038 species, depth, port, etc.). Since catch and effort per sampled trip are both obtained, the  
1039 dockside survey of ORBS was also used to develop an index of abundance for China rockfish.

1040 Modifications had to be made to trip hours from the original ORBS dataset to create a  
1041 standardized unit of effort. Since trip hours in ORBS are not hours fished, as in MRFSS,  
1042 but rather the total duration of the trip (as measured from the time the boat crossed into the  
1043 ocean until the time they were interviewed at the dock), travel times had to be determined  
1044 and subtracted from trip hours in order to get a standardized measure of fishing effort per  
1045 trip. Accordingly, a total distance function was created for each trip based on the river  
1046 miles (distance along the navigable channel from the port to the bar (river mouth)) and  
1047 ocean miles (i.e., straight distance from the river bar to the ocean grid fished, wrapping  
1048 around obstructions if needed). Total distance was then converted to travel time based on  
1049 generalized vessel speeds for private (i.e., 18 mph) and charter boats (i.e., 13 mph) provided  
1050 by Wayne Butler (Oregon charter captain; personal communication). It is important to note  
1051 that the original trips hours minus travel hours still does not equal hours fished because it  
1052 does account for time needed to move from drift to drift; however, since the number of resets  
1053 between drifts would be expected to be related to fish abundance (as with catch rates),

1054 the modified trips hours was deemed a viable effort unit for the assessment. Some trips  
1055 had erroneous trips hours (discrepancies between values entered on paper and then entered  
1056 electronically later). These were the steps taken to correct the issue:

- 1057 1. Trip hours is computed automatically by the data logger based on the time the inter-  
1058 view is entered electronically
- 1059 2. If samplers write their interviews on paper and enter them electronically later when  
1060 they have time (as believed to have happened despite being instructed not to), then  
1061 the trip hours are inflated.
- 1062 3. To potentially remove these errors, we computed time intervals between interviews.  
1063 Pulses of interviews a minute or two apart are very likely to have been from bunches  
1064 of paper interviews entered at electronically in one sitting, as normal interviews are  
1065 somewhat sporadic and take more than a minute to complete.

1066 The ORBS dockside charter boat records (years 2001-2014) include 36,752 trips in the un-  
1067 filtered data set, of which 4,080 caught China rockfish (11%). As with the other trip-based  
1068 CPUE data sets, the Stephens-MacCall method was used to identify trips with a high prob-  
1069 ability of catching China rockfish. Prior to using the Stephens-MacCall approach to select  
1070 relevant trips, a number of other filters were applied to the data to minimize variability in  
1071 CPUE estimates. Criteria for valid trips included vessels with 20+ sampled trips (13% of  
1072 vessels accounted for 89% of trips) and trip hours <12. Trips targeting tuna and dive trips  
1073 were excluded from the analysis (see Table 20 for other filters).

1074 As with the MRFSS indices, potentially informative species for the Stephens-MacCall analy-  
1075 sis were defined as those occurring in at least 30 unique trips, in 10 different years (Figure 33).  
1076 Some of these never occurred with China rockfish (strong ‘counter-indicators’) and records  
1077 with these species were removed from the data prior to estimation of the index. Strong  
1078 counter-indicators for the ORBS data set included blue shark, white sturgeon, steelhead,  
1079 and albacore. Trips in which at least 99% of the catch consisted of pelagic rockfish were also  
1080 excluded, as anglers were likely targeting semi-pelagic rockfish (Table 20).

1081 Coefficients from the Stephens-MacCall analysis identified several rockfish species (black,  
1082 rosy, tiger, bocaccio, vermillion, yelloweye, copper, etc.) as indicators of positive China  
1083 rockfish catch, along with lingcod, kelp greenling, and cabezon. Counter-indicators included  
1084 deep-water rockfish, salmonids, and Pacific Halibut. Brown rockfish, another nearshore  
1085 rockfish species, was among the counter-indicator species, reasons for which are unclear to  
1086 the STAT at this time.

1087 A total of 6232 trips were retained following the Stephens-MacCall filter (Table 21). Model  
1088 selection with AIC proceeded as with the other dockside indices, but the ORBS data sup-  
1089 ported an interaction term in the lognormal component of the delta-GLM (Table 22). The  
1090 interaction was not supported by the binomial model (although AIC retained a region effect),  
1091 but the keeping the year-region interaction term in the positive model reduced the AIC by  
1092 38 points over a model with year and region alone (Table 22).

1093 To account for this interaction, separate delta-GLM models (each with a year and wave  
1094 effect) were fit to the regional data (Southern OR and Northern OR, split at Florence). The  
1095 regional indices show little change in the northern region, but a decline in catch rates in  
1096 the south (Figure 34). Residual diagnostics for the regional models did not show strong  
1097 deviations from model assumptions in either area (Figures 35 and 36). Estimated area of  
1098 rocky reefs off Oregon was generated using GIS (see description of onboard observer indices),  
1099 and we calculated an area-weighted index based on the relative proportion of reef habitat in  
1100 each region (total reef habitat distributed as 35.4% north, 64.6% south).

1101 The final, area-weighted index (Table 23, Figure 37) shows a declining stock (on average,  
1102 statewide), but the STAT emphasizes that this does not capture regional patterns in CPUE,  
1103 and may underestimate the fishing impacts in the southern region, and overestimate impacts  
1104 in the north.

#### 1105 2.1.6 Fishery-Dependent Data: Recreational Onboard Observer Surveys

1106 The goal of the Observer Programs in California and Oregon is to collect data including  
1107 charter boat fishing locations, catch and discard of observed fish by species, and lengths of  
1108 discarded fish. Both states sample the commercial passenger fishing vessel (CPFV), i.e., char-  
1109 ter boat or for-hire fleet. The onboard observer programs collect drift-specific information  
1110 at each fishing stop on an observed trip. At each fishing stop recorded information includes  
1111 start and end times, start and end location (latitude/longitude), start and end depth, num-  
1112 ber of observed anglers (a subset of the total anglers), and the catch (retained and discarded)  
1113 by species of the observed anglers. Data for the onboard observer indices for the recreational  
1114 CPFV fleet are from four sampling programs.

1115 The CDFW conducted an onboard observer program in central California from 1987-1998  
1116 (Reilly et al. 1998). These data were previously used in the 2013 data moderate assessments  
1117 (Cope et al. 2015), at the level of a fishing trip. Since the 2013 assessments, the original  
1118 data sheets were acquired and data were keypunched to the level of fishing stop. One caveat  
1119 of this data is that location data were recorded at a finer scale than the catch data. We  
1120 aggregated the relevant location information (time and number of observed anglers) to match  
1121 the available catch information. Between April 1987 and July 1992 the number of observed  
1122 anglers was not recorded for each fishing stop, but the number of anglers aboard the vessel is  
1123 available. We imputed the number of observed anglers using the number of anglers aboard  
1124 the vessel and the number of observed anglers at each fishing stop from the August 1992-  
1125 December 1998 data (see Appendix E for details, p.E-1). In 1987, trips were only observed  
1126 in Monterey, CA and were therefore excluded from the analysis. CDFW collected lengths of  
1127 both retained and discarded fish during this time period. All China rockfish measured were  
1128 retained and lengths are used as length compositions for this index.

1129 California implemented a statewide sampling program in 1999 (Monk et al. 2014). California  
1130 Polytechnic State University (Cal Poly) has conducted an independent onboard sampling  
1131 program as of 2003 for boats in Port San Luis and Morro Bay (Stephens et al. 2006), but

1132 follows the protocols established in Reilly et al. (1998), and modified to reflect sampling  
1133 changes that CDFW has also adopted, e.g., observing fish as they are landed instead of at  
1134 the level of a fisher's bag. Therefore, the Cal Poly data area incorporated in the same index  
1135 as the CDFW data from 1999-2014. CalPoly collects lengths of both retained and discarded  
1136 fish.

1137 We generated separate relative indices of abundance in California for the 1987-1999 and  
1138 2000-2014 datasets due to the number of regulation changes occurring throughout the time  
1139 period (see Appendix H, p.[H-1](#)). CDFW implemented a regulation of three hooks in 2000,  
1140 which was reduced to (and remains at) two hooks in 2001.

1141 The ODFW initiated an onboard observer program in 2001, which became a yearly sampling  
1142 program in 2003 (Monk et al. 2013). Both California and Oregon provided onboard sampling  
1143 data through 2014. Both of these programs only collected lengths of discarded fish, and the  
1144 number of lengths of China rockfish from these studies is small (Figure [38](#)).

1145 All indices were standardized using a delta-GLM modeling approach (Lo et al. 1992). Data  
1146 were analyzed at the drift level and catch was taken to be the sum of observed retained and  
1147 discarded fish, i.e., number of fish encountered per angler hour. The onboard observer data  
1148 from the CDFW 1999-2014 data between north of 40°10' N. latitude and the Oregon border  
1149 were too sparse to include in the index. Therefore, indices used in the model with a break  
1150 at 40°10' N. latitude remain the same as the state-specific onboard observer indices.

#### 1151 *Data Filtering*

1152 Prior to any analyses, a preliminary data filter was applied.

1153 Trips/drifts from the CDFW 1988-1998 meeting the following criteria were excluded from  
1154 analyses:

- 1155 1. Drift associated with a fishing location code that was not assigned to a reef
- 1156 2. Drifts identified as having possible erroneous location, observed anglers, or time data
- 1157 3. Trips encountering <50% groundfish species (number of fish)

1158 Trips/drifts from the ODFW, CDFW 1999-2014, and Cal Poly databases meeting the fol-  
1159 lowing criteria were excluded from analyses:

- 1160 1. ODFW halibut-targeted trips were excluded
- 1161 2. Drifts south of Pt. Conception (only 2 China rockfish observed south of Pt. Conception)
- 1162 3. Trips encountering <50% groundfish species
- 1163 4. Drifts within the current Stonewall Bank Yelloweye Rockfish Conservation
- 1164 5. Drifts within Arcata Bay, Humboldt Bay, South Bay, or San Francisco Bay
- 1165 6. Drifts missing a starting location (latitude/longitude)
- 1166 7. Drifts identified as having possible erroneous location or time data
- 1167 8. Drifts missing both starting and ending depths
- 1168 9. Drifts within the habitat data occurring farther than 83 m from a reef in Oregon and 34
- 1169 m in California (see Appendix F (p. [F-1](#)) for details)
- 1170 10. Drifts outside the habitat data in California occurring farther than 141 m from reef (see
- 1171 Appendix F (p. [F-1](#)) for details)

- 1172 11. Drifts occurring on a reef with <3 positive encounters of China rockfish  
1173 12. Drifts occurring on a reef in which China rockfish was observed in <25% of years the  
1174 reef was visited

1175 **Index standardization: Oregon**

1176 At the March 2015 Nearshore Stock Assessments Workshop the issue of hook saturation by  
1177 black rockfish (*Sebastodes melanops*) in Oregon was raised ([Agenda Item D.8 Attachment 10](#),  
1178 June 2015). The recreational fishery in Oregon specifically targets black rockfish. While black  
1179 rockfish associate with rocky habitat, they are a schooling, midwater species. Fishermen  
1180 specifically targeting black rockfish may not drop their lines to the seafloor, or may encounter  
1181 black rockfish and other midwater species before their lines can reach the seafloor. To address  
1182 this issue in the onboard observer data, we filtered out drifts for which the catch (retained  
1183 plus discarded) consisted of at least 95% black, blue (*Sebastodes mystinus*) and yellowtail  
1184 (*Sebastodes flavidus*) rockfishes, the most commonly occurring midwater rockfish species. This  
1185 resulted in a decrease in the number of drifts by 4,092, only three of which observed China  
1186 rockfish.

1187 The filtered dataset included 6,038 drifts, of which 259 (4%) drifts with positive encounters  
1188 (Table 24). The majority of drifts sampled (75%) were from north of Florence, although  
1189 China rockfish were present in 6% of drifts in southern Oregon and 3% of drifts in the north.  
1190 Covariates considered in the full model included *year*, *depth*, *month* or *2-month wave* and,  
1191 *region* (Figures 39 and 40). To increase sample sizes data from waves 2 and 3 were aggregated  
1192 as well as from 4 and 5 (ODFW does not sample in waves 1 and 6). Depths greater than 20  
1193 m were also binned to 20-59 m.

1194 The final selected dataset contained categorical variables for *year* (13 levels), *wave* (2 levels),  
1195 *region* (2 levels, north and south of Florence), and three depth bins (*depth*: 0-19 m, and  
1196 20-59 m). A lognormal model was selected over a gamma for the positive encounters by a  
1197 deltaAIC of 20.01. Model selection, using AIC, selected a lognormal model with *year*, *wave*,  
1198 *depth*, *region*, and a *wave:depth* interaction, while a binomial with *year*, *region*, and *wave*  
1199 was selected (Table 25). In the lognormal submodel, stepwise BIC retained the *year*. In  
1200 the binomial model, stepwise BIC retained *region* and *wave*. The final *year* effects from the  
1201 delta-GLM with main effects *year*, *region*, and *wave* are shown in Table 26 and Figure 41).  
1202 The final model suggests that relative abundance was slightly higher in southern Oregon,  
1203 and in waves 4 and 5. Standard model diagnostics show adequate fit and general consistency  
1204 with GLM model assumptions for the positive catch component (Figure 42).

1205 **Index standardization: California**

1206 *Central California 1988-1998*

1207 The filtered dataset included 5,557 drifts, of which 852 (15%) drifts with positive encounters  
1208 (Table 24). To increase sample sizes, data from Regions 2 and 3 were aggregated as well as  
1209 Regions 8 and 9. Samples north of Ten Mile River were too sparse to reliably include in the  
1210 index.

1211 Covariates considered in the full model included *year*, *depth*, *month or 2-month wave* and,  
1212 *region* (Figures 43 and 44). The selected data contained categorical variables for *year* (13  
1213 levels), *wave* (6 levels), *region* (5 levels), and four depth bins (*depth*: 0-19 m, 20-39 m, 40-59 m,  
1214 and 60-79 m). A lognormal model was selected over a gamma for the positive encounters by a  
1215 deltaAIC of 125.06. Model selection, using AIC, selected a lognormal model with *year*, *depth*,  
1216 *and region*, while a binomial with *year*, *region*, *depth*, *wave*, and a *year:region* interaction was  
1217 selected. However, the standard errors of the binomial model with interactions were large,  
1218 and suggested data were too sparse to explore the *year:region* interaction. For the lognormal  
1219 submodel, stepwise BIC retained the *depth* and *region* (Table 27). For the binomial submodel,  
1220 stepwise BIC retained *year*, *region*, and *depth*. The final *year* effects from the delta-GLM with  
1221 main effects *year*, *region*, and *depth* are shown in Table 28 and Figure 45). The covariates in  
1222 the final model suggest the relative abundance of China rockfish decreases with depth and  
1223 increases north of Monterey, CA. Standard model diagnostics show adequate fit and general  
1224 consistency with GLM model assumptions for the positive catch component (Figure 46)

1225 *California (north of Pt. Conception) 2000-2014*

1226 The filtered dataset included 13,993 drifts, of which 1,403 (10%) drifts with positive encoun-  
1227 ters (Table 24). CDFW began sampling Region 12 (Trinidad Head to the OR border) in  
1228 2008 and no trips from Region 11 (Cape Mendocino to the Eel River) were sampled from  
1229 2000-2014. From 2008-2014, only 10 drifts encountering China rockfish were observed in  
1230 Region 12. Therefore, the following index only reflects the population south of Cape Mendo-  
1231 cino. Further, to increase sample sizes drifts from Regions 2 and 3 were aggregated as well  
1232 as Regions 7 and 8, and Regions 9 and 10.

1233 Covariates considered in the full model included *year*, *depth*, *month or 2-month wave* and,  
1234 *region* (Figures 47 and 48). The selected data contained categorical variables for *year* (15  
1235 levels), *wave* (6 levels), *region* (6 levels), and four depth bins (*depth*: 0-19 m, 20-39 m, 40-59  
1236 m, and 60-79 m). A lognormal model was selected over a gamma for the positive encounters  
1237 by a deltaAIC of 115.91. Model selection, using AIC, selected a lognormal model with *year*,  
1238 *depth*, *and region*, while a binomial with *year*, *region*, *depth*, and a *year:region* interaction was  
1239 selected. However, the standard errors of the binomial model with interactions were large,  
1240 and suggested data were too sparse to explore the *year:region* interaction. For the lognormal  
1241 submodel, stepwise BIC retained the *year* and *region* (Table 29). For the binomial submodel,  
1242 stepwise BIC retained *region*, and *depth*. The final *YEAR* effects from the delta-GLM with  
1243 main effects *year*, *region*, and *depth* are shown in Table 30 and Figure 49). The covariates  
1244 in the final model suggest the relative abundance of China rockfish decreases with depth,  
1245 specifically in depths greater than 59 m, and increases south to north. Standard model  
1246 diagnostics show adequate fit and general consistency with GLM model assumptions for the  
1247 positive catch component (Figure 50)

1248 **2.1.7 Fishery-Independent Data: sources considered, but not used in assess-**  
1249 **ment**

1250 *Northwest Fisheries Science Center (NWFSC) slope survey*

1251 The NWFSC slope survey was conducted annually from 1999 to 2002. The depth range of  
1252 this survey (100-700 fm) is outside the depth range of China rockfish, and was therefore not  
1253 used in this assessment.

1254 *Northwest Fisheries Science Center (NWFSC) shelf-slope survey*

1255 This survey is referred to as the “combo,” conducted annually since 2003. The survey  
1256 consistently covered depths between 30 and 700 fm, and has never encountered a China  
1257 rockfish. Therefore, the combo survey was not used in this assessment.

1258 *Alaska Fisheries Science Center (AFSC) shelf survey*

1259 The survey, often referred to as the “triennial” survey was conducted every third year between  
1260 1977 and (and conducted in 2004 by the NWFSC using the same protocols). The triennial  
1261 survey trawls in depths (generally 30 to 275 fm) that are deeper the range and habitats of  
1262 China rockfish, and was therefore not used in this assessment.

1263 *Pikitch study*

1264 The Pikitch study was conducted between 1985 and 1987 (Pikitch et al. 1988). The northern  
1265 and southern boundaries of the study were 48°42' N latitude and 42°60' N. latitude respec-  
1266 tively, which is primarily within the Columbia INPFC area (Pikitch et al. 1988 , Rogers and  
1267 Pikitch 1992). Participation in the study was voluntary and included vessels using bottom,  
1268 midwater, and shrimp trawl gears. Observers of normal fishing operations on commercial  
1269 vessels collected the data, estimated the total weight of the catch by tow and recorded the  
1270 weight of species retained and discarded in the sample. China rockfish are not targeted using  
1271 trawl gear, and therefore we did not use data from this survey in the assessment.

1272 *Enhanced Data Collection Project (EDCP)*

1273 The EDCP was conducted by ODFW to collect information on bycatch and discard ground-  
1274 fish species off the coast of Oregon from late 1995 to early 1999. EDCP had limited spatial  
1275 coverage in Oregon waters only. China rockfish are not targeted using trawl gear, and  
1276 therefore we did not use data from this survey in the assessment.

1277 *Partnership for Interdisciplinary Studies of Coastal Oceans (PISCO)*

1278 A total of 59 China rockfish were observed in 17,657 SCUBA transects conducted in the  
1279 southern and central survey regions. Transects were conducted in Northern California and  
1280 Oregon for two years (2010-2011), with a higher occurrence of China rockfish (156 out of  
1281 956 transects).

1282 **2.1.8 Biological Data: Length and age compositions**

1283 Length compositions were provided from the following sources, by region, with brief descrip-  
1284 tions below:

1285 Southern model (*south of 40°10' N. latitude*)

- 1286 • Jeff Abrams' thesis (*research, 2010-2011*)
- 1287 • CALCOM (*commercial dead fish, 1992-2006, excluding 1999*)
- 1288 • CALCOM (*commercial live fish, 1997-2012*)
- 1289 • CDFW onboard observer (*recreational charter, 1987-1998*)
- 1290 • California recreational sources combined (*charter mode, 1960, 1978-2014*)
  - 1291 – Miller and Gotshall survey
  - 1292 – CA rec. sampling (1978-1985)
  - 1293 – MRFSS (1980-2003)
  - 1294 – CRFS (2004-2014)
- 1295 • California recreational sources combined (*private mode, 1959 and 1980-2014*)
  - 1296 – Miller and Gotshall survey
  - 1297 – CA recreational sampling (1978-1985)
  - 1298 – MRFSS (1980-2003)
  - 1299 – CRFS (2004-2014)
- 1300 • CCFRP (*research, Point Buchon to Año Nuevo, 2007-2013*)
- 1301 • WCGOP (*discards, 2004-2013*)

1302 Central model (*California north of 40°10' N. latitude to the OR/WA border*)

- 1303 • ORBS north of Florence (*recreational, charter and private modes, 1980-2014*)
- 1304 • ORBS south of Florence (*recreational, charter mode, 1984-2014*)
- 1305 • ORBS south of Florence (*recreational, private mode, 1980-2014*)
- 1306 • PacFIN Oregon (*commercial live fishery, sexes combined, 1998-2014*)
- 1307 • PacFIN Oregon (*commercial dead fishery, sexes combined, 1995-2014*)
- 1308 • CALCOM (*commercial dead fish, 1992-2002*)
- 1309 • CALCOM (*commercial live fish, 1997-2010*)
- 1310 • California recreational sources combined (*charter and private modes, 1981-2014*)
  - 1311 – MRFSS (1981-2003)
  - 1312 – CRFS (2004-2014)

1313 Northern model (*Washington state MCAs 1-4*)

- 1314 • Washington MCAs 3-4 (*recreational all modes, 1979-2014*)
- 1315 • Washington MCAs 1-2 (*recreational all modes, 1969-2014*)

1316 Recreational: Washington (WDFW)

1317 Recreational length- and age- composition data were provided directly from WDFW during winter 2015. The WDFW routinely collected recreational biological samples for Chinook rockfish between 1995 and 2014, with all but one year sampled during 1979 to 1983. These 1318 composition data lack information on the number of fish sampled out of those landed in 1319 a given trip, and therefore are used without expansion to the sample level. Unexpanded 1320 recreational composition data are frequently used in West Coast stock assessments for the 1321 above reason. Length and age data collected from dockside recreational samples WA are 1322 1323

1324 summarized by the number of fish sampled (Table 31). The WA recreational length- and  
1325 age- compositions are shown in Figures 51, 52, 9, and 53.

1326 *Recreational: California MRFSS and CRFS length composition data*

1327 Individual fish lengths recorded by MRFSS (1980-2003) and CRFS (2004-2011) samplers were  
1328 downloaded from the RecFIN website ([www.recfin.org](http://www.recfin.org)). CRFS data from 2012-2014 were  
1329 obtained directly from CDFW. Fish were assigned to the northern and southern management  
1330 areas based on county and interview site number. To examine finer scale spatial differences  
1331 in size composition data, interview sites in each county were assigned to a CRFS district  
1332 (including years prior to 2004). Distributions of lengths increased from south to north, with  
1333 the largest change in mean length occurring between CRFS districts 5 & 6 (roughly around  
1334 Cape Mendocino; Figure 54). This pattern was consistent across all years of CRFS sampling  
1335 (2004-2014; Figure 55). Sizes of retained fish north of Cape Mendocino were more similar  
1336 to fish caught in Oregon than fish caught south of Cape Mendocino. Since both biological  
1337 (e.g. growth) and fishery-related (e.g. selectivity, retention) factors can influence the size  
1338 compositions, length at age was estimated internal to the assessment models in all three  
1339 areas.

1340 *Recreational: Oregon Recreational Boat Survey (ORBS)*

1341 Biological data from the ORBS program were provided by ODFW. The ORBS is a dockside  
1342 sampling program for the both the recreational CPFV and private modes. Length compo-  
1343 sition samples from north of Florence for the CPFV and private fleets were provided from  
1344 1980-2014. Samples from south of Florence spanned 1984-2014. Distributions of length data  
1345 from these southern and northern parts of Oregon were similar to each other, and across  
1346 years (Figure 56).

1347 *Recreational: Miller and Gotshall (1965)*

1348 The Northern California Marine Sport Fish Survey conducted an assessment survey with  
1349 goals that included estimation of annual fishing effort by all recreational fishing modes,  
1350 catch by weight, CPUE, and collection of data to analyze length compositions. Lengths  
1351 from 101 China rockfish were collected from 1959-1960. Lengths of China rockfish from 1959  
1352 primarily came from private/rental boats, and lengths from 1960 came from charter boats.  
1353 These two years of data were not consistent with length composition data from later years,  
1354 and were influential on model results (see model sensitivities to these data).

1355 *Commercial: PacFIN (Oregon and California)*

1356 Biological data from commercial fisheries for China rockfish were extracted from PacFIN  
1357 (PSMFC) on May 18, 2015. Commercial landings and the biological characteristics of hook-  
1358 and-line landings were sampled from 1995-2014 in Oregon and in 1991-2013 California. There  
1359 is no commercial catch of China rockfish in the state of Washington. Currently, port biol-  
1360 ogists employed by each state fishery agency collect species-composition information and  
1361 biological data from the landed catches. The monitoring programs currently in place vary  
1362 between the states but are generally based on stratified, multistage sampling designs. The  
1363 OR data were available by live fish fishery landings and dead fish fishery landings, but fish

1364 conditions were not available for PacFIN for the CA landings. Due to the lack of fish condition  
1365 data for CA in PacFIN, the CA commercial fishery compositions were downloaded from  
1366 the [CALCOM](#) database.

1367 Annual commercial length- and age-frequency distributions were developed for each state for  
1368 which observations were available, following the same bin structure as was used for research  
1369 observations. For each fleet, the raw observations were expanded to the sample level, to  
1370 allow for any fish that were not measured, then to the trip level to account for the relative  
1371 size of the landing from which the sample was obtained. Length and age data collected from  
1372 commercial landings for OR and CA are summarized by the number of port samples (Tables  
1373 [32](#) and [33](#)). Figures [57](#), [58](#), [59](#), [60](#), [61](#), and [62](#) show plots of the commercial length and age  
1374 composition data for the central model. Figures [63](#), [64](#), and [65](#) show plots of the commercial  
1375 length and age composition data for the southern model.

1376 *Research: NMFS groundfish ecology survey*

1377 From 2001-2005, the SWFSC Fisheries Ecology Division conducted longline surveys aboard  
1378 a chartered commercial longline vessel at various stations between Monterey and Davenport,  
1379 CA (36° N. latitude to 37.5° N. latitude)(pers. comm. Don Pearson, SWFSC). Longline gear  
1380 was set in various depths from 10 meters to 700 meters, parallel to the depth contour. Each  
1381 longline set consisted of 3-5 skates, each with about 250 2/0 circle hooks baited with squid.  
1382 In nearshore habitats, we allowed the gear to soak for roughly 30 minutes. A small number  
1383 of China rockfish length samples were available from this cruise, but were not included in  
1384 the assessments due to sample size and potential differences in selectivity.

1385 *Research: California Collaborative Fisheries Research Program (CCFRP)*

1386 The [California Collaborative Fisheries Research Program](#) (CCFRP), created by Rick Starr  
1387 (Sea Grant and Moss Landing Marine Laboratory) and Dean Wendt (Cal Poly San Luis  
1388 Obispo), monitors marine protected areas (MPAs) and gathers information useful for fisheries  
1389 management (Starr et al. 2015). This program has been running in Central California since  
1390 2007. Length compositions for China rockfish were included in this assessment (Figure [66](#)).

1391 Future research is planned to use CPUE information from this program, comparing relative  
1392 abundance indices derived from fishery-dependent and fishery-independent monitoring pro-  
1393 grams. The CCFRP data provide a time series of fishery-independent catch and effort at  
1394 fixed stations, collecting information at sample sites inside and outside of MPAs spanning  
1395 about 200 miles of the California coast from Point Buchon to Año Nuevo. This fishery-  
1396 independent information, combined with our current fishery-dependent information (i.e.,  
1397 CPFV onboard observer data), provides an opportunity for fine-scale spatial and temporal  
1398 analysis of catch rates and species compositions, specifically addressing the research needs  
1399 identified in nearshore rockfish stock assessments.

1400 *Research: Abrams Thesis*

1401 Jeff Abrams (2014) conducted a research study aboard recreational charter boats from Cres-  
1402 cent City Harbor, Trinidad Bay and the Noyo River Harbor. Rocky habitat was identified

1403 from high resolution bathymetric data and gridded into 500 m by 500 m cells (California  
1404 Seafloor Mapping Project, data available from: <http://seafloor.ottrelabs.org/index.html>).  
1405 During a sampling event, cells were randomly selected to fish. Fish were captured via hook-  
1406 and-line by either researchers, students, or recreational fishers. The charter boat captain  
1407 was not allowed to search and target fish within the cell. Fishing drifts started at the up-  
1408 current/wind side of the cell and drifted to the opposite edge of the cell, then stopped the  
1409 clock and reset for another drift (Jeff Abrams, pers. comm.) If it was certain that fishing  
1410 was occurring over sand, the captain would generally reset. However, because cells were  
1411 selected with a minimum area of rocky habitat, this was rare. This study provided 138  
1412 individual China rockfish, which were used as Conditional Age-at-Length (CAAL) in the  
1413 southern model (Figure 67).

#### 1414 2.1.9 Biological Data: Age structures

1415 Age structure data were available from the following sources:

1416 *Southern model (California south of 40°10' N latitude)*

- 1417 • Jeff Abrams' thesis (*research*, 2010-2011)
- 1418 • CDFW (*recreational and research*, 1972-1985)
- 1419 • CDFW (*recreational CPFV*, 1977-1986)
- 1420 • CDFW (*recreational CPFV*, 1980-1984)
- 1421 • NMFS groundfish ecology (*research*, 2003-2005)

1422 *Central model (California north of 40°10' N latitude to the OR/WA border)*

- 1423
- 1424 • Oregon, majority south of Florence (*commercial dead landings*, 2001-2013)
  - 1425 • Oregon, north of Florence (*recreational, all modes combined*, 2005-2013)
  - 1426 • Oregon, south of Florence (*recreational, all modes combined*, 2005-2013)

1427 *Northern model (Washington state MCAs 1-4)*

- 1428
- 1429 • Washington South (MCAs 1-2, *recreational, all modes combined*, 2014)
  - Washington North (MCAs 3-4, *recreational, all modes combined*, 1998-2014)

1430 The commercial ages from Oregon were extracted from PacFIN, and these data are uploaded  
1431 by the states. The Washington state ages were provided by Tien-Shui Tsou (pers. comm.)  
1432 and aged by WDFW. Otoliths from various CDFW sampling programs (1972-1985) were  
1433 aged for this assessment. It is unclear whether the otoliths were obtained from recreational  
1434 boat modes, research cruises, and diving modes. For this reason, these ages were not included  
1435 in the assessment models, but were used for external estimation of size at age. Commercial  
1436 port samplers in California sampled catch from recreational charter boats in the late 1970s  
1437 and early 1980s.

1438 A total of 3,963 fish were aged/re-aged for this assessment (Table 34), very few of which  
1439 were small or young fish(Figure 69). Prior to this assessment, the only available growth

1440 curve for China rockfish was estimated from Lea et al. (1999). Lea et al. (1999) aged China  
1441 rockfish via the surface aging method. Surface ages are biased towards younger ages; the  
1442 break-and-burn method is preferred and more precise (Beamish 1979, Kimura et al. 1979).  
1443 All ages for this assessment were aged using the break-and-burn method, either by WDFW  
1444 or the NMFS NWFSC Aging Lab.

1445 Length-at-age was initially estimated external to the population dynamics models using the  
1446 von Bertalanffy growth curve (Bertalanffy 1938),  $L_i = L_\infty e^{(-k[t-t_0])}$ , where  $L_i$  is the length  
1447 (cm) at age  $i$ ,  $t$  is age in years,  $k$  is rate of increase in growth,  $t_0$  is the intercept, and  $L_\infty$   
1448 is the asymptotic length. The unavailability of small fish results in unrealistic estimates  
1449 of  $t_0$ , on the order of -9 to -20 depending on the subset of data modeled. For exploratory  
1450 purposes,  $t_0$  was fixed at 0, and for final estimates of growth the length of age-0 fish was  
1451 fixed at 2 cm. The NMFS SWFSC conducts an annual rockfish recruitment and ecosystem  
1452 assessment survey. Pelagic juvenile rockfish are collected at an average age of approximately  
1453 100 days. The mean size of all rockfish species at 1 month of age was roughly 2 cm. At  
1454 this age, length-at-age is fairly consistent among species and therefore differences in growth  
1455 among species are unlikely to introduce considerable bias. We approximated size-at-age zero  
1456 in the assessment with a value of 2 cm.

1457 Differences in growth between sexes, among fleets, and regions were explored. To remove  
1458 biases introduced by region or fleet, we used data from the southern Oregon (south of  
1459 Florence, OR) commercial (dead fish) fleet to look at the growth difference between males  
1460 and females. Few fish were aged older than 37 years (5.8%). For ages in which there were  
1461 fish aged older than 37 years, there was only one fish in each age. Including these fish  
1462 in the model proved to bias the von Bertalanffy growth estimates (large ( $>1.5$ ) standard  
1463 errors in estimates of  $L_\infty$ ). Therefore, the following exploratory analyses exclude fish older  
1464 than 37 years. Fixing  $t_0$  at 0, the other parameters for males and females were similar and  
1465 the differences were not biologically significant, (Males:  $L_\infty = 37.14, k = 0.21$ ; Females:  
1466  $L_\infty = 35.91, k = 0.23$ ). This result, estimating males having a larger asymptotic size of  
1467 approximately 1 cm than females, is anomalous, as females are larger than males in all but  
1468 one rockfish species (Love et al. 2002). This is also inconsistent with the analysis of Lenarz  
1469 and Echeverria (1991), which identified no significant sexually dimorphic characters in China  
1470 rockfish. Quillback rockfish (*Sebastodes maliger*, also in the *Pteropodus* subgenus) are also long-  
1471 lived and don't exhibit dimorphic growth until approximately age 30, with an estimated  $L_\infty$   
1472 of 0.5 cm greater for females than males (Love et al. 2002). Given the sparse data for older  
1473 China rockfish and the unlikelihood of China rockfish being the only rockfish species where  
1474 males are larger than females, growth is assumed the same for males and females in this  
1475 assessment.

1476 Using data from southern Oregon (south of Florence, OR), differences in growth among  
1477 the commercial (dead fish) and the private recreational fleets were explored. There were  
1478 significant differences in growth between the fleets (Commercial:  $L_\infty = 36.23, k = 0.22$ ;  
1479 Recreational:  $L_\infty = 37.93, k = 0.22$ ), suggesting differing selectivity between the fleets.  
1480 The commercial fleet has been restricted to a 12 in minimum size limit since 2000, with a

1481 preference for plate-sized fish. All of the age data from the southern Oregon commercial  
1482 (dead fish) fleet are from 2001-2013. The recreational fleet has no minimum size limit and  
1483 all samples are from 2005-2013.

1484 Regional differences in growth were significant. In general, the asymptotic size of fish were  
1485 smallest in southern California (south of 40°10' N. latitude), increased in northern California  
1486 (north of 40°10' N. latitude) to southern Washington (MCAs 1 & 2) and decreased again in  
1487 northern Washington (Table 35 and Figure 70).

1488 Stock Synthesis models growth as the Schnute parameterization of the von Bertalanffy  
1489 growth model. The size of fish at age-0 was fixed at 2 cm with a CV of 0.1, and all other  
1490 parameters estimated within the model.

### 1491 2.1.10 Biological Data: Aging precision and bias

1492 Ageing imprecision was estimated using a collection of 529 China rockfish otoliths with  
1493 multiple age reads (Figures 71 - 73). We analyzed this data set using the ageing error  
1494 software provided by Andre Punt and Jim Thorson, publicly available at <https://github.com/nwfsc-assess/nwfscAgeingError>. The software estimated a bias in the age readings  
1495 from some early samples read by a former NWFSC age reader and these were excluded from  
1496 the compositions used in the model. The variability in age readings of the remaining readers  
1497 was estimated under an assumption of a linear increase in standard deviation with age. The  
1498 resulting estimate indicated a standard deviation in age readings increasing from 0.1 years  
1499 at age 1 by about 1 year of uncertainty per 10 years of age to a standard deviation of 7.7  
1500 years at age 80.

### 1502 2.1.11 Biological Data: Weight-Length

1503 The weight-length relationship is based on the standard power function:  $W = \alpha(L^\beta)$  where  
1504  $W$  is individual weight (kg),  $L$  is length (cm), and  $\alpha$  and  $\beta$  are coefficients used as constants.

1505 This assessment uses weight-length parameters for females of  $\alpha = 1.17 \times 10^{-5}$  and  $\beta = 3.177$ ,  
1506 derived from Lea et al. (1999). A fit of the length-weight relationship to the Oregon ORBS  
1507 data,  $\alpha = 2.06 \times 10^{-5}$  and  $\beta = 3.02$ , yielded a curve that was very similar to that reported in  
1508 Lea et al. (1999)(Figure 74).

### 1509 2.1.12 Biological Data: Maturity and Fecundity

1510 China rockfish maturity-at-length data were sparse and was gathered from two available  
1511 sources, one from California and one from Oregon. Echeverria (1987) collected 69 China  
1512 rockfish from central and northern California, of which the age at first maturity was 3 years  
1513 for males and females (26 cm). Both males and females exhibited 50% maturity at 4 years  
1514 (27 cm) and 100% maturity at 6 years (30 cm).

1515 In Oregon, Hannah and Blume (2011) determined a length at 50% maturity at 28.5 cm from  
1516 a sample size of 239 China rockfish. Maturity was fit to a logistic curve,  $p_l = \frac{e^{B_0+B_l l}}{1+e^{B_0+B_l l}}$ ,  
1517 where  $p_l$  is the proportion of the natural fish at length  $l$ , and  $B_0$  and  $B_1$  are the regression  
1518 coefficients. Parameter estimates from Hannah and Blume (2011) are  $B_0 = -13.320$  and  
1519  $B_1 = 0.467$ .

1520 The southern base model used the California estimate (50% mature at 27cm) while the  
1521 central and northern draft based models used the Oregon estimate (50% mature at 28.5 cm).  
1522 Fecundity is assumed proportional to female spawning biomass in the draft base models.

### 1523 2.1.13 Biological Data: Natural Mortality

1524 Natural mortality for wild fish populations is extremely difficult to estimate.

1525 Dick and MacCall (2010) estimated natural mortality for 50 data poor stocks using Hoenig's  
1526 (1983) method. The total mortality rate ( $Z$ , the sum of natural and fishing mortality rates),  
1527 is estimated as,  $\log(Z) = 1.710 - 1.084\log(A_{max})$ , where  $A_{max}$  is the maximum observed age.  
1528 The mortality rate was back-transformed to arithmetic space using a bias correction factor,  
1529 log-scale standard deviation of 0.4.

1530 Cope et al. (2015) used the maximum age for China rockfish of 79 years in the 2013 data  
1531 moderate assessment, which produces a natural mortality rate of 0.055. The maximum age  
1532 of China rockfish on the West Coast is now 83 years (age data for this assessment), which  
1533 gives a natural mortality of 0.056 when calculated from Hoenig's method.

### 1534 2.1.14 Biological Data: Sex ratios

1535 The sex ratio from all of the aged China rockfish for this assessment were approximately  
1536 50% each males and females (WA:47%, OR:47%, and CA: 49% female). These fishes came  
1537 from a mixture of recreational, commercial, and research collections.

## 1538 2.2 History of Modeling Approaches Used for this Stock

### 1539 2.2.1 Previous assessments

1540 Dick and MacCall (2010) estimated the overfishing level (OFL) for China, which was adopted  
1541 for the PFMC's 2011-12 and 2013-14 management cycles, as components of the stock complex  
1542 OFLs associated with each species.

1543 China rockfish was assessed as a data moderate species in 2013 (Cope et al. 2015). The  
1544 accepted assessment modelled removal and index data using Extended Depletion-Based Stock  
1545 Reduction Analysis (XDB-SRA) (Dick and MacCall 2011), which is a Bayesian surplus  
1546 production model reparameterized in terms of MacCall's (2009) Depletion-Corrected Average

1547 Catch method. The STAR panel favored regional models for China rockfish, north and south  
1548 of  $40^{\circ}10'$  N. latitude.

1549 The stock north of  $40^{\circ}10'$  N. latitude was found to be below target biomass, as a percentage of  
1550 unfished biomass (a.k.a. “depletion”), but above the minimum stock size threshold (MSST).  
1551 The median of the posterior northern spawning biomass in 2013 was estimated at 37% (84  
1552 mt), and the fishing mortality rate in 2012 was 21.5% of  $F_{MSY}$ .

1553 The stock south of  $40^{\circ}10'$  N. latitude was found to be above target biomass, as a percentage  
1554 of unfished biomass (a.k.a. “depletion”). The median of the posterior southern spawning  
1555 biomass in 2013 was estimated at 66% (264 mt), and the fishing mortality rate in 2012 was  
1556 27% of  $F_{MSY}$ .

## 1557 2.2.2 Spatial stock structure

1558 The waters and biological communities of the California Current System tend to exhibit the  
1559 greatest change at the major promontories along the West Coast, including Point Conception,  
1560 Cape Mendocino, Cape Blanco and the northern tip of Vancouver Island (Checkley and Barth  
1561 (2009); Hickey (1979); Gottscho (2014)). In particular, the waters off Cape Mendocino are  
1562 a known biogeographical boundary along the West Coast of the U.S. and has been shown  
1563 as a geographical boundary across a number of terrestrial and marine taxa (see Gottscho  
1564 (2014) for a review). The waters off Cape Mendocino, CA are characterized by turbulent  
1565 waters and some of the strongest winds and upwelling found within the California Current  
1566 (Botsford and Lawrence 2002, Pacific Fishery Management Council 2013).

1567 The California Current is the equatorward surface flow that extends from the Vancouver  
1568 Island, Canada (approx.  $50^{\circ}$  N. latitude) with equatorward flow to Baja California, Mexico  
1569 (approx.  $15^{\circ} - 25^{\circ}$  N. latitude) (Hickey 1979, Checkley and Barth 2009). Winds associated  
1570 with the North Pacific High, the Aleutian Low, and a thermal low-pressure system drive the  
1571 oceanographic dynamics that stretch from central California to northern Mexico (Checkley  
1572 and Barth 2009). Seasonal winds drive the frequency and intensity of upwelling along the  
1573 coast. Off the coast of Washington south to Cape Blanco, OR the winds and therefore  
1574 upwelling is generally weak. Starting near Cape Blanco, OR the continental shelf narrows  
1575 and winds and upwelling intensity increases (Francis et al. 2009). The winter environment  
1576 south of Cape Mendocino is dominated by upwelling from southerly winds pushing water  
1577 offshore through Ekman transport, whereas northward winds north of Cape Mendocino result  
1578 in downwelling. Summer upwelling is dominant along the entire West Coast of the US from  
1579 the northerly winds pushing the surface waters offshore via Ekman transport. South of  
1580 Cape Mendocino upwelling conditions persist all year, with the northerly winds strongest  
1581 from April-June. North of Cape Mendocino a low pressure system in the Gulf of Alaska  
1582 produces westerly and southwesterly winds that blow surface waters towards shore and result  
1583 in downwelling.

1584 In addition to the oceanic conditions in the California Current, there is also a prominent  
1585 submarine ridge off the coast of Cape Mendocino. The Mendocino Escarpment, a submarine

ridge extending past the 200 nm EEZ boundary, is a dominant physical feature in the California Current (Fisk et al. 1993). Currents from the north and south converge around the Mendocino Escarpment creating an area of offshore transport, which may create a physical barrier to larval dispersal (Magnell et al. 1990, Cope 2004, Sivasundar and Palumbi 2010).

Gottsch (2014) completed a comprehensive review of the zoogeography literature worldwide and identified both Cape Mendocino and Point Conception as phylogeographic breakpoints on the West Coast. Specifically, coastal Oregon does not experience the intense upwelling and offshore transport as off the California coast south of Cape Mendocino, which allows increased larval retention in nearshore waters in Oregon (Gottsch 2014). Drake (2013) used simulation modelling to evaluate dispersal of spring spawning nearshore invertebrates and found that larval dispersal ranged from 175 km to 200 km from the release site (Bodega Bay, CA) when larvae remained below the surface boundary layer, allowing larvae to avoid offshore drifts. Larval retention in nearshore waters in California may be driven by the timing of relaxed upwelling and the ability of larvae to remain below the surface boundary layer (Sivasundar and Palumbi 2010, Drake and Edwards 2013). In simulations, larval dispersal ranged from 175 km to 200 km from the release site (Bodega Bay, CA) when larvae remained below the surface boundary layer, which allows larvae to avoid offshore advection (Drake and Edwards 2013). The majority of drifters released off the coast of Oregon (Newport and Coos Bay) from 1994-1999 remained north of Cape Mendocino within the first 40 days of deployment and none returned to coastal waters south of Point Arena, CA (Sotka et al. 2004). Trajectories of comparative drifters released in off the coast of Santa Barbara, CA never overlapped with the drifters released in Oregon.

Cape Blanco and Cape Mendocino have both been shown as transition zones to juvenile and adult fishes. Field and Ralston (2005) utilized landings and age data to elucidate year-class strength among a number of rockfish species along the West Coast. Spatial patterns in recruitment were heightened in vicinity Cape Mendocino and Cape Blanco versus comparison between regions further from these capes. Characterization of species assemblages in two of the trawl surveys conducted by the NMFS have also shown shifts around Cape Mendocino. Tolimieri (2006) found a shift in the species assemblage captured in the NMFS slope trawl survey near both Point Conception Cape Mendocino, CA and Cape Blanco, OR. The AFSC triennial shelf trawl surveys indicate a change in distribution around the Mendocino Escarpment; with the Mendocino Escarpment acting as a physical barrier to some species, e.g., blackgill rockfish, Pacific ocean perch, chilipepper, shortbelly rockfish, bocaccio, and greenspotted rockfish (Williams and Ralston 2002).

In addition to analyzing fisheries catch and survey trawl data, results from recent genetic studies of rockfish along the West Coast vary from finding genetic divergence along the coast to finding little evidence of genetic divergence along the coast. Genetic studies of blue rockfish, a nearshore midwater species with schooling tendency, show the species to have a genetic break around Cape Mendocino, CA (Cope 2004, Burford and Bernardi 2008). A study by Sivasundar and Palumbi (2010) confirmed a genetic differentiation of blue rockfish between Oregon and Monterey, CA, with yellowtail rockfish exhibiting the same strong genetic differ-

1627 entiation. While Sivasundar and Palumbi (2010) did not specifically look at China rockfish,  
1628 the *Pteropodus* subgenus was represented by copper, gopher and brown rockfishes, all three  
1629 of which exhibited only moderate genetic differentiation along the coast. Additional genetic  
1630 studies of copper, grass and brown rockfishes indicate limited larval dispersal and increasing  
1631 genetic divergence with increasing geographic distance [Buonaccorsi (2002); Buonaccorsi et  
1632 al. (2004); Buonaccorsi unpubl. data]. Much additional work is needed to fully understand  
1633 the genetic differentiation of rockfish species along the west coast. However, these studies  
1634 support the hypotheses that oceanographic and physical barriers are likely to limit larval  
1635 dispersal along the coast.

1636 California has managed the area from Cape Mendocino to the Oregon/California border as  
1637 its own management area since 2000 (see Appendices G and H for details). The Pacific  
1638 Fishery Management Council developed a Pacific Coast Fishery Ecosystem Plan in which  
1639 the California Current Large Marine Ecosystem and recognizes the transitional zone between  
1640 Cape Blanco, OR and Cape Mendocino, CA (Francis et al. 2009, Pacific Fishery Management  
1641 Council 2013).

1642 The 2013 stock assessment of China rockfish consisted of two, independent models, north  
1643 and south of 40°10' N. latitude. Following the STAR panel, a request was made to stratify  
1644 the assessment north and south of 42° N. latitude (the CA-OR border), based on concerns  
1645 over spatial differences in exploitation history and insufficient trend data between 40°10' N.  
1646 latitude and 42° N. latitude ([Agenda Item F.5.b Supplemental GMT Report](#), June 2013). In  
1647 November 2013, after examining results from both area stratifications, the SSC concluded  
1648 that there was no evidence in support of either stratification, and recommended that the  
1649 Council retain the model stratified around the existing management boundary ([Agenda Item](#)  
1650 [H.5.b Supplemental SSC Report](#), November 2013).

1651 The 2013 China rockfish assessment was a data-moderate assessment and therefore did not  
1652 consider size and age composition data as part of the analysis. For this assessment, the  
1653 STAT made efforts to examine all available data sources that might provide evidence of  
1654 spatial stock structure. Data sets with sufficient sample sizes and spatial coverage included  
1655 length frequency and length at age data.

1656 The largest source of length composition data came from the recreational fleets in each state.  
1657 In California, the California Recreational Fisheries Survey (CRFS) has collected length data  
1658 by CRFS district since 2004. Distributions of length for sampled (retained) catch varied  
1659 by district, with mean length smallest in the southernmost district with adequate samples  
1660 (CRFS District 3), and largest in the northernmost district, CRFS District 6, roughly the  
1661 area between Cape Mendocino and the California-Oregon border (Figure 55). There is some  
1662 indication of a gradient in average length of retained fish, but the largest increase in mean  
1663 length between adjacent CRFS Districts occurs between CRFS Districts 5 & 6 (roughly  
1664 across Cape Mendocino).

1665 Since length compositions of retained fish are affected by numerous processes (e.g., growth,  
1666 recruitment, exploitation, selectivity), the STAT also compared growth curves fit to size at  
1667 age data. External fits indicated differences in growth among regions, and these patterns

1668 were consistent with growth curves estimated within the assessment models (see base model  
1669 results for details).

1670 **2.2.3 2013 Data Moderate Recommendations**

1671 **Recommendation 1:** Continued research on the uncertainty in the catch histories  
1672 of all groundfishes. Reconstructions of historical catches are still needed  
1673 for certain areas, time periods, and fisheries. Currently, reconstructed  
1674 catches are available for California's commercial and recreational fisheries  
1675 extending back to 1916 and 1928, respectively (Ralston et al. 2010).  
1676 Oregon has completed a reconstruction for its commercial catch since 1876  
1677 (V. Gertseva, NMFS; pers. comm.), but recreational catch prior to 1980  
1678 is assumed to be zero in this analysis. Recreational catch in Washington  
1679 was reconstructed to 1975 for these assessments, and interpolated back to  
1680 1960. A thorough reconstruction of historical commercial catches (prior  
1681 to 1981) is urgently needed for Washington. Estimates of uncertainty in  
1682 historical catch reconstructions are needed for all states.

1683  
1684 2015 STAT response: Oregon completed a reconstruction of the recreational catches  
1685 back to 1973. There is currently no reconstruction of the commercial catches in Wash-  
1686 ington, and no estimates of uncertainty are available for any catch reconstruction.

1687 **Recommendation 2:** Single-species stock assessment models are still unable to  
1688 address systematic changes in productivity due to external factors such  
1689 as inter-species relationships and low-frequency aspects of climate change.  
1690 Relatively simple data-moderate models may provide tractable linkages to  
1691 ecosystem models, and are relatively easy to modify to reflect ecosystem  
1692 forces.

1693  
1694 2015 STAT response: No additional ecosystem or environmental data were included in  
1695 the 2015 China rockfish assessment.

1696 **Recommendation 3:** Exploration of trans-boundary assessments with Canada  
1697 should be initiated, and would benefit all parties. This also requires  
1698 development of data inputs including historical catch reconstructions. Due  
1699 to their transparency, data-moderate assessments may play an especially  
1700 useful role in promoting trans-boundary fishery science.

1701  
1702 2015 STAT response: Canada has not conducted a stock assessment for China rockfish.

1703 **Recommendation 4:** The data-moderate assessments assume known catches,  
1704 but there is considerable uncertainty in historical catch reconstructions,

1705 particularly for the recreational fishery. This uncertainty has not been  
1706 measured, and tools for incorporating this uncertainty in assessments are  
1707 not well developed. This is an issue for all assessments.

1709 2015 STAT response: See response to the first recommendation.

1710 **Recommendation 5:** There are fundamental differences between XDB-SRA and  
1711 exSSS in how stock productivity is modeled. For exSSS, FMSY increases  
1712 as the ratio of BMSY/B0 decreases in a deterministic way, while there  
1713 is no prior relationship between FMSY and the ratio of BMSY/B0 for  
1714 XDB-SRA. It is unclear which of these assumptions is most appropriate.  
1715 This is a broader issue than for just data-moderate assessments, since  
1716 it questions the appropriateness of two-parameter curves such as Bever-  
1717 ton-Holt to model the stock recruit relationship. Research to improve  
1718 understanding of the relationship between the inputs of the XDB-SRA and  
1719 exSSS productivity parameters is encouraged.

1720  
1721 2015 STAT response: The 2015 China rockfish assessment assumes a Beverton-Holt  
1722 stock-recruit relationship, with a fixed value for steepness in all three models. The  
1723 STAT agrees with the recommendation, and considers this a priority for “off-year”  
1724 research.

1725 **Recommendation 6:** Different priors (uniform of q / uniform on log-q) for the  
1726 additional variance term were used in the two assessment models. It is  
1727 unclear which performs best, and, since this term affects the weights given  
1728 to each index in the model fitting, the form of the prior will influence  
1729 model results, particularly when the indices are in conflict.

1730  
1731 2015 STAT response: Additional variance parameters were estimated for all indices in  
1732 the China rockfish models, but no explicit prior was used in Stock Synthesis, apart  
1733 from specifying parameter bounds.

1734 **Recommendation 7:** Compare the standardized (onboard observer) indices from  
1735 the proposed method with indices constructed by applying the Stephens--  
1736 MacCall approach to the data aggregated by trip.

1737  
1738 2015 STAT response: Time constraints have not allowed for this analysis and it is a  
1739 priority research topic for the next off-cycle year.

1740 **Recommendation 8:** The GMT representative also recommended expanding  
1741 the analysis of CPUE data to additional sectors of the recreational fishery,  
1742 such as private and rental boats. CPUE indices from these sectors may be

1743 useful in future assessments of nearshore stocks.

1744

1745 2015 STAT response: Time constraints did not allow a private-mode index for the  
1746 California recreational dockside survey. Oregon and Washington both provided data  
1747 for the private/rental and party/charter recreational fleets from dockside surveys. A  
1748 private boat mode index was considered for Oregon, but rejected due to infrequent  
1749 catches of China. The WA recreational index included boat mode (charter and private)  
1750 as a categorical variable in the delta-GLM analysis.

1751

1752 **Recommendation 9:** The GMT representative noted that for certain nearshore  
1753 species there is potential utility in using post-2003 RecFIN dockside  
1754 data as well as onboard sampling data since depth restrictions have not  
1755 constrained access to the adult population.

1756

1757 2015 STAT response: The 2015 China rockfish assessment utilizes data through 2014  
1758 for the onboard observer programs in California and Oregon. The California post-  
1759 2003 dockside data were not used because a large percentage of the trips north of Pt.  
1760 Conception were also sampled by the onboard observer program.

1761 **Recommendation 10:** The Panel strongly emphasizes the value of conducting  
1762 a data workshop during which catches, indices, biology, and other data  
1763 inputs are reviewed.

1764

1765 2015 STAT response: The China STAT team participated in the Nearshore Stock  
1766 Assessment Workshop held March 31-April 2, 2015 in Portland, OR.

1767 **Recommendation 11:** The historical CPFV drift-specific data should be key-  
1768 punched, which should allow the algorithm for developing CPFV-based  
1769 data indices to be improved.

1770

1771 2015 STAT response: The SWFSC Fisheries Ecology Division key-punched and error-  
1772 checked the CDFW 1987-1998 onboard observer survey data. These data were included  
1773 in an onboard index.

1774 **Recommendation 12:** Recommendation: Habitat maps should be developed so  
1775 that structural rather than true zeros are designated using data which are  
1776 independent from the data used to determine the indices.

1777

1778 2015 STAT response: Habitat maps and 'reefs' were defined by the SWFSC using the  
1779 California Seafloor Mapping Project and the Oregon State waters Mapping Program  
1780 mapping products. These habitat maps were used to select data for the onboard  
1781 observer indices in both California and Oregon.

1782 **2.3 Response to the 2015 STAR Panel Requests**

1783 **Request No. 1: Explore the utility of using California Recreational Fisheries  
1784 Survey (CRFS) data from 2004-2007 to partition California catches in the  
1785 early years based on the proportion of catch in the private recreational and  
1786 charter modes north and south of 40°10' N latitude (concerns the southern  
1787 and central models).**

1788

1789 **Rationale:** This may be a better alternative to the current approach of using logbook  
1790 data to partition the recreational catches north and south of 40°10' N latitude.

1791 **STAT Response:** This request was not completed, and was repeated as request no.  
1792 13.

1793 **Request No. 2: Add the current assessment biomass trends for current base  
1794 model to the plot in the draft assessment that compares the XDB-SRA  
1795 and SS3 runs and plot an additional set of runs for all models where  
1796 steepness and natural mortality are estimated with priors (add results  
1797 from the northern and central models). This would be two sets of plots  
1798 with spawning biomass and depletion (all models).**

1799

1800 **Rationale:** To provide a comparison between the previous assessment results using  
1801 XDB-SRA and the current assessment. XDB-SRA has more flexible productivity as-  
1802 sumptions than SS3, so estimating h and M was regarded as a way to more closely  
1803 mimic XDB-SRA using stock synthesis.

1804 **STAT Response:** The plots were provided (Figures 75 and 76). Since XDB-SRA  
1805 had knife-edge maturity at age 5, summary biomass for ages 5 and older was used  
1806 in the plot to provide a common basis for comparison. For the southern model, the  
1807 SS3 model with estimated h and M and XDB-SRA show similar results in absolute  
1808 summary biomass and depletion. For the north plus central models, it was not possible  
1809 to simultaneously estimate h and M, but again the results were similar.

1810 **Request No. 3: Compare the amount of available habitat for China rockfish in  
1811 the area covered by northern and central models with estimates of  $R_0$  for  
1812 the northern and central models.**

1813

1814 **Rationale:** Available habitat by region may provide an independent proxy for the  
1815 relative abundance of the stock in each region.

1816 **STAT Response:** Available rocky habitat was examined using two methods, and  
1817 ratios of habitat between areas showed an increase in habitat from the northern area,  
1818 to the central area, and to southern area with the most habitat. The Panel regarded this  
1819 as a useful exercise for ranking assessment areas, but it cannot be used for determining

relative abundance. There were a number of methodological issues that would need to be addressed to do this more rigorously, and ultimately its application to stock assessment would be indirect given the assumptions required. The Panel will consider making a research recommendation to examine the estimated area of reefs at more finely resolved scales.

**Request No. 4: Provide a model run where historical discards for the live-fish fishery are modeled as a separate fleet. For the discard fleet, estimate actual tonnage of catch: apply the discard fraction for the earliest four years to estimate discards back to 2000 with a ramp from 1990 to 2000 (selectivity for this fleet is determined from the discard length comps) (southern model only).**

**Rationale:** Fits to discard amount for the live-fish fishery by the model since 2000 are poor, and the model structure does not allow flexibility to decrease the discards prior to 2000.

**STAT Response:** This was done. Fits generally improved and the estimated selectivity pattern for the discard fleet appeared reasonable. The STAR Panel and the STAT agreed that the base model should incorporate this new approach.

**Request No. 5: Provide the proportion of trips removed using the Stephens--MacCall filter over time as a diagnostic for all area models.**

**Rationale:** To evaluate potential bias in the filtering procedure.

**STAT Response:** This was done for the northern area, and proportion of trips retained showed a temporal pattern of a slight increase followed by a decline in number of trips retained. The STAT asked that this request be considered a low priority for the other areas because it was not clear what the patterns in proportion of trips retained would indicate, and the northern area model was not sensitive to index treatment. The Panel agreed. Further investigation is needed and this will be added to the list of research recommendations. Examination of the characteristics of trips retained/removed using the Stephens-MacCall method should be a routine part of index standardization.

**Request No. 6: For the central model, provide a run where the northern California size composition data are added to the model, estimate two selectivity parameters (i.e., the simpler selectivity function), and estimate M to understand how this affects fits to the length composition data. Provide residual plots.**

**Rationale:** This may produce a selectivity pattern that has a more realistic peak (full selection of a reasonable portion of observed lengths).

1858           **STAT Response:** The selectivity pattern improved but estimates a very high M  
1859           (0.12) and produces an implausible estimate of biomass (>1000 times the base model).  
1860           The model is not supportable as a change to the base model.

1861       **Request No. 7: Exclude the Marine Recreational Fisheries Statistics Survey**  
1862       **(MRFSS) index in Oregon to define a new base case for the central model.**

1863

1864

1865           **Rationale:** It was learned that multiple intercept interviews were done for a single  
1866           trip, so the index was not constructed from trip level data, as was intended. This only  
1867           affects MRFSS index for Oregon.

1868           **STAT Response:** Excluding this index had a minor effect on model results. This  
1869           problem should be correctable so the STAR panel will list this as a research recommen-  
1870           dation.

1871       **Request No. 8: Add in the northern California length composition data to**  
1872       **central area model. The selectivity pattern for this fishery should mirror**  
1873       **the southern Oregon selectivity pattern. Retune the length composition**  
1874       **data.**

1875

1876           **Rationale:** These data were inadvertently left out of the model.

1877           **STAT Response:** This was done. Adding these data had a minor effect on model  
1878           results.

1879       **Request No. 9: For the central area model, attempt to estimate the selectivity**  
1880       **patterns for each fishery and determine which of the selectivity patterns**  
1881       **provides plausible estimates. Take the mean of those estimates (peak**  
1882       **and/or spread parameters) and use the mean as a prior for the poorly**  
1883       **estimated selectivities. Consider using the mode of the observed length**  
1884       **distribution as a prior for the peak parameter.**

1885

1886           **Rationale:** To provide a more objective means to reflect selectivity parameters for  
1887           those fleets where those parameters cannot be estimated.

1888           **STAT Response:** Alternative procedures resulted in models with small difference  
1889           to the base case depletion, though scale is dependent on the choice of peak value for  
1890           selectivity for parameters that were required to be fixed (highest estimated value that  
1891           didn't hit the bound of 45 cm). The Panel agreed that the original procedure used for  
1892           the base case was simple and more supportable from a methodological viewpoint.

1893       **Request No. 10: For the central area model, repeat Request No. 9 using a two**  
1894       **parameter ascending logistic curve for selectivity.**

1895

1896     **Rationale:** To examine the effect on model results of using a different functional form  
1897     for asymptotic selectivity.

1898     **STAT Response:** Logistic curves did not improve model results, and all the same  
1899     issues remain.

1900     **Request No. 11: Turn on estimation of recruitment deviations for all models,  
1901     and iteratively increase  $\sigma_R$  from a low value until the residual pattern  
1902     stabilizes.**

1904     **Rationale:** To determine whether estimating recruitment deviations can be supported  
1905     by any of the models.

1906     **STAT Response:** All models estimated extremely large recruitments in the 1980s  
1907     and early 1990s that seem implausible and are not obvious in size composition data.  
1908     For the southern area model, the standard error of recruitment deviance is larger than  
1909      $\sigma_R$  for many early estimates, which is a nonsensical result. The likelihood components  
1910     show slightly worse fit to indices, an improved fit for age composition data, and the  
1911     most improvement for size composition data. This suggests that the estimated recruit-  
1912     ment deviations are being driven by relatively subtle signals in the length composition  
1913     data rather than improved ability to fit the trends in the indices. The Panel concluded  
1914     that there was insufficient information to estimate recruitment deviations for all mod-  
1915     els. Therefore no changes were made to the base model. One potential area of research  
1916     for data-moderate stocks would be evaluate the effect of assuming different levels au-  
1917     tocorrelation in the stock-recruit relationship. This might help curb the tendency to  
1918     estimate extreme recruitment with sparse datasets.

1919     **Request No. 12: For all models, explore alternative methods of reweighting the  
1920     conditional age-at-length data, but do not increase the weight on any data  
1921     set. Alternatives to evaluate are: the unmodified sample size (the method  
1922     used for the base case), and Francis weighting method A and B (report the  
1923     values of A and B).**

1925     **Rationale:** Methods for weighting conditional age-at-length data are a current active  
1926     area of research with no generally agreed procedures, so model sensitivity to each  
1927     method requires examination.

1928     **STAT Response:** For the southern area model the weights for both the Francis A and  
1929     B methods were above one, so no reweighting was applied. For both the central and  
1930     the northern area models, Francis method A for the most part strongly downweights  
1931     the conditional age-at-length data. The situation is most extreme for the northern  
1932     area model, where iterative application of Frances method A appeared to be leading  
1933     to a zero weight being given to conditional age-at-length data. Weighting is highly  
1934     influential on both absolute biomass and relative depletion.

1935 The Francis method A appears to produce unrealistically small weights for conditional  
1936 age-at-length data in some cases. Apparently Francis method A is the recommended  
1937 approach in preference to method B (C. Francis, pers. comm.), but the Panel was  
1938 unable to find clear rationale for this recommendation. The harmonic mean method  
1939 has a history of use and theoretical basis in the multinomial distribution, and generally  
1940 provides weightings that are intermediate to no weighting (unmodified initial otolith  
1941 counts) and the Frances method A. The Panel recommended that the harmonic mean  
1942 should be used for now as it provides a compromise between no weighting and Francis A,  
1943 while noting that a workshop with a focus on these methods later this year may result  
1944 in the general recommendation of one of the existing methods or a new procedure.

1945 **Request No. 13:** Explore the utility of using California Recreational Fisheries  
1946 Survey (CRFS) data from 2004-2007 to partition California catches in the  
1947 early years based on the proportion of catch in the private recreational  
1948 and charter modes north and south of 40°10' N latitude (this concerns the  
1949 southern and central models). This is a repeat of Request No. 1.

1950  
1951 **Rationale:** This may be a better alternative to the current approach of using logbook  
1952 data to partition the recreational catches north and south of 40°10' N latitude.

1953 **STAT Response:** This analysis was completed. South of 40°10' N latitude, the  
1954 difference in model results between using CRFS data and logbook for the apportioning  
1955 catches is small. North of 40°10' N latitude there is a greater difference, primarily a  
1956 change in initial stock size. The logbook method was based on data collected over  
1957 a long period of time, while the CRFS method is based only on recent data. The  
1958 logbook method better captures temporal changes in fishery, while CRFS method pro-  
1959 vides better information on relative catches between private and charter boats. In  
1960 Oregon, recreational fishing for nearshore rockfish began around 1970, and this should  
1961 be indicative of northern California. The STAR panel and STAT agreed that the log-  
1962 book method should be used because the reconstructed catches are more consistent  
1963 with what is known about the gradual development of the recreational fishery in north-  
1964 ern California. Nevertheless, the Panel flagged improved methods for reconstructing  
1965 recreational catches as a research recommendation.

1966 **Request No. 14:** A set of revised base models should be brought forward with  
1967 the following recommended changes:

- 1968
- 1969 • Use weight specific fecundity relationships from Dick (2009) for all  
1970 models.
  - 1971 • Update 2011 and 2012 data in the onboard observer CPUE index  
1972 (southern model).
  - 1973 • Change the years in the Abrams dataset to 2010-2011; remove obser-  
1974 vations N of 40°10' N latitude (southern model).

- Model discards as a separate fleet (southern model).
- Remove Oregon MRFSS index (central model).
- Add northern California length composition data (central model).
- Fix any selectivity parameters hitting upper bounds (central model).

**Rationale:** All of these changes have been identified and agreed to as changes that need to be made to the base models.

**STAT Response:** The changes were implemented to establish a new set of base models for China rockfish.

**Request No. 15: Tune all models using the harmonic mean method for the conditional age-at-length composition and marginal age composition data.**

**Rationale:** The Panel recommended that the harmonic mean method be used to re-weight the conditional age-at-length composition data, because it is a well-understood and frequently applied method that provided intermediate results compared to other alternatives.

**STAT Response:** This was done and considered appropriate as a new base model.

**Request No. 16: Estimate M in the revised base models for southern and northern models, and use the average of those estimates as a fixed value for all models.**

**Rationale:** The northern and southern area models (but not the central area model) provide some objective basis for the selection of an appropriate value for M.

**STAT Response:** Although the estimates of M for the northern and southern area models are reasonable, the estimate for the central area M (0.116) is difficult to support. The age composition data are noisy, but fits suggest that more young fish are observed than would be expected for lower values of M, outweighing the effect of older fish on the fits, which results in the preference towards a higher M in this model. There are a good number of observations of older fish that arguably are more important in terms of stock status that should be fitted by the model, and only the lower M values provide a reasonable fit to the oldest age observations. Values of M of 0.09 and above lead to unrealistically high biomass and minimal effect of fishing, results which appear to conflict with the habitat-based relative biomass among models. The median of the prior for M is 0.05 for this stock, and it is unclear why the data are so informative about the value of M. The northern and southern area models have more age data than the central area model, and the abundance indices show contrast, which is not apparent in the central area indices. Consequently the northern and southern area models may provide more supportable values for M. The Panel's proposed approach is to use the average of the estimated M values for the southern and northern area models (0.07) as a fixed value for all assessments.

2014   **Request No. 17:** Provide likelihood profiles for M in all revised base models;  
2015    consider providing a combined likelihood profile in one graphic for all  
2016    models.

2017

2018   **Rationale:** Since the estimated values for M may be used as fixed value in all assessments, the Panel would like the STAT to examine the likelihood profiles as a useful diagnostic.

2019   **STAT Response:** Likelihood profiles for both the southern and northern area models appear quite reasonable, particularly the northern area model where both the index data and the age data support the estimated M value. It should be noted that since these models are not estimating recruitment deviations, they are highly constrained, and may provide misleadingly precise estimates compared to models with greater flexibility.

2020   **Request No. 18:** Normalize all indices and provide time series plots in which groups of comparable indices are plotted together (southern and central models). Provide time series plots in which groups of comparable index residuals are plotted together.

2031

2032   **Rationale:** To assess the comparability of indices prior to incorporation in the assessment model.

2033   **STAT Response:** This was done, see Figures 77 and 78. In the southern area model, overall trends are broadly consistent with the model biomass and show a decline to the late 1990s, followed by an increase. The model has the ability to scale the periods before and after 2000 due a lack of overlap of indices in this period. The observer CPFV index shows a sustained decline after 2005 that the model is unable to match, even when recruitment deviations are turned on. Because China rockfish is a very long-lived species, age-structured population dynamics precludes rapid changes in abundance when fishing is relatively stable, suggesting that there must be some other cause for this recent trend. Indices for the central area show similar pattern from 2000 to 2014 across three indices that are also difficult to account for with China rockfish population dynamics. The Panel discussed potential interactions with other species (e.g., black rockfish) due to hook competition, and regulatory changes as factors that could affect CPUE indices derived from a multi-species recreational fishery. Panel will add a research recommendation that these factors be investigated.

2048   **Request No. 19:** Provide likelihood profiles on M for all base models, which  
2049    now are using a fixed value of M of 0.07. Plot predicted spawning output  
2050    on the M profile plots.

2051

2052   **Rationale:** To evaluate whether the profiles for M for the base models for the northern  
2053    and southern area are well determined as a justification using a single fixed value across

2054 all models, and to also demonstrate the inadequacy of the central model for estimating  
2055 M

2056 **STAT Response:** This was done. The new base models behaved as expected (except  
2057 for spawning output declining at very high M for southern area model).

2058 **Request No. 20:** Provide bracketing model runs varying M (high and low Ms  
2059 should be equidistant from the base M (high M = 0.09; base M = 0.07; low  
2060 M = 0.05 (set to the median of the prior)) for potential decision tables.  
2061 Assume projected ACL removals for a category 2 stock ( $P^* = 0.45, \dots = 0.72$ , 40-10 adj. as needed) applied to high and low M scenarios. Also  
2062 provide projected ACL removals under base case, and recent year catches  
2063 (if different than base case ACLs).

2065 **Rationale:** Development of a potential axis of uncertainty based on M.

2066 **STAT Response:** This was done.

2068 **Request No. 21:** Update the figures from Request No. 2 with the new base  
2069 models (show summary biomass).

2071 **Rationale:** To provide a comparison between the previous assessment results using  
2072 XDB-SRA and the current assessment.

2073 **STAT Response:** This was done (Figure 79). The current base models deviate more  
2074 strongly from the results using XDB-SRA than the pre-STAR models, but results  
2075 remain broadly consistent (i.e., biomass estimates differ by no more than a factor of  
2076 two).

2077 **Request No. 22:** Provide runs of for the central model treating all age com-  
2078 positions as marginal (fix growth parameters, and alternatively fix and  
2079 estimate M).

2081 **Rationale:** This may provide improved fits to composition data, and may also provide  
2082 further evidence that large values for M above 0.1 for the central model are implausible.

2083 **STAT Response:** Results were only very slightly different to the base model, so no  
2084 additional information was provided for the assessment.

2085 **Request No. 23:** Provide two runs from the base for the southern area model  
2086 that bracket uncertainty in steepness. Use values of 0.6 and 0.9 which  
2087 are close to the 12.5 and 87.5 percentiles from the Thorson prior. Pro-  
2088 vide projected biomass to compare with current bracketing models with M.

2090 **Rationale:** To determine whether uncertainty in M sufficiently captures uncertainty  
2091 for decision tables for the southern area model.

2092       **STAT Response:** This was done. The bracketing model runs for steepness and M  
2093        produced remarkably similar results, allowing the Panel to agree to use only M to  
2094        bracket uncertainty for management advice for the southern area model, and to do the  
2095        same for the northern and central area models.

2096       **Request No. 24:** The STAR panel requested a detailed justification be provided  
2097        for the decisions regarding stock structure assumed in the assessment(s)  
2098        (i.e., growth differences, size composition, fishery discard rates, evidence  
2099        of low larval drift, and management history and jurisdiction).

2100       **Rationale:** This information was not provided in detail in the draft assessment doc-  
2101        ument. This is just a bookkeeping request as the Panel had discussed with the STAT  
2102        the importance of providing supporting information on stock structure decisions, but  
2103        no formal request was forwarded to the STAT.

2104       **STAT Response:** This information will be included in the final assessment document.

2105       

## 2.4 Model Description

2106       

### 2.4.1 Transition from the 2013 to 2015 stock assessment

2108       The first formal assessment of China rockfish was conducted as a data moderate assessment  
2109       in 2013 (Cope et al. 2015). The results of the 2013 assessment were based on catch histories  
2110       and indices of abundance from onboard (OR and CA) and dockside (OR and CA) surveys of  
2111       the recreational fishing fleet. Below, we describe the most important changes made since the  
2112       last full assessment and explain rationale for each change. [Note: descriptions below apply  
2113       to the pre-STAR base model, and were not modified to reflect the final base model in order  
2114       to provide a record of events leading to selection of the final model]:

- 2115       1. Population dynamics model changed from a Bayesian surplus production model (XDB-  
2116       SRA) with two areas (U.S. waters north and south of 40°10' N. latitude) to a length-  
2117       based, age-structured statistical catch at age model (Stock Synthesis) with three areas  
2118       (U.S. waters south of 40°10' N. latitude, 40°10' N. latitude to the OR-WA border, and  
2119       from the OR-WA border to the U.S.-Canadian border). *Rationale:* The assessment  
2120       is moving from a data moderate to a full assessment, incorporating new data sources,  
2121       e.g. individual growth, age and length compositions of landed and discarded catch.
- 2122       2. New point estimate for annual natural mortality rate (0.053). *Rationale:* median of a  
2123       prior distribution derived from a method endorsed by the SSC (O. Hamel, NWFSC;  
2124       pers. comm.).

- 2125 3. Beverton-Holt stock-recruitment relationship with steepness fixed at 0.773. *Rationale*:  
2126 when estimated, steepness in the model approaches implausible values (near 1). Al-  
2127 though uncertainty in model results is greatly underestimated, steepness in each sub-  
2128 model was fixed at the mean of a prior distribution derived from a meta-analysis of  
2129 rockfish steepness parameters (J. Thorson, NWFSC; pers. comm.).
- 2130 4. Revised catch histories for California, Oregon, and Washington. *Rationale*: agency  
2131 representatives for each state either prepared (OR and WA) or reviewed (CA) revised  
2132 catch histories for the commercial and recreational fisheries.
- 2133 5. Updated indices of abundance through 2014. *Rationale*: following research recommen-  
2134 dations from the last assessment, current indices include revised recreational CPUE  
2135 based on spatially-referenced, onboard observer data combined with habitat data, as  
2136 well as catch and effort data by fishing-stop from the 1988-1999 CDFW onboard ob-  
2137 server program.
- 2138 6. Two new recreational dockside CPUE indices for northern Washington (1981-2014)  
2139 and Oregon (2004-2014). *Rationale*: previous assessment had no trend information  
2140 for Washington state, and did not include CPUE from the high-intensity dockside  
2141 sampling program in Oregon (ORBS).
- 2142 7. New commercial logbook CPUE index for the southern Oregon nearshore fishery (2004-  
2143 2013). *Rationale*: previous assessment contained no indices of abundance based on  
2144 commercial fisheries data. This (primarily live-fish) nearshore fishery has expanded  
2145 rapidly over the past two decades.
- 2146 8. Models include new age data representing all three states. *Rationale*: allows growth to  
2147 be estimated in each sub-model based on conditional-age-at-length composition data.
- 2148 9. Discards modeled explicitly with selectivity and retention curves in the southern area  
2149 model. *Rationale*: new length composition data for discarded catch permits explicit  
2150 modeling of retention and selectivity in the southern commercial live-fish fishery.

2151 Prior to the STAR Panel review meeting, age-structured production models (i.e., fit only  
2152 to indices of abundance) were developed in Stock Synthesis to mimic the XDB-SRA mod-  
2153 els from the 2013 stock assessment. Trends in stock status and overall scale were similar  
2154 among models for the northern substock (Figures 80 and 81), but the southern substock  
2155 was estimated to have a larger unfished biomass and similar current biomass (i.e. a more  
2156 depleted stock) when the data were fit in Stock Synthesis (Figures 82 and 83). The age-  
2157 structured model makes different assumptions from the last assessment about production  
2158 (Beverton-Holt stock-recruitment relationship, with steepness estimated at 0.88 and 0.89 in  
2159 the northern and southern models, respectively) and growth, which may explain the differ-  
2160 ences between the two population dynamics models. See Request #2 from the 2015 STAR  
2161 Panel for a comparison of final base model results to the 2013 assessment.

2162 **2.4.2 Definition of fleets and areas**

2163 We generated data sources for each of the models. Fleets include:

2164 **Northern Model**

2165 *Recreational*: All catch in the northern model is recreational. The recreational fleets include  
2166 separate landings from the party/charter and private./rental modes in MCAs 3-4 and com-  
2167 bined party/charter and private/rental modes for MCAs 1-2 (where catches and sample sizes  
2168 were lower).

2169 **Central Model**

2170 *Commercial*: The commercial fleets include five separate fleets, one each for the live and dead  
2171 commercial fishers in the following areas, California north of 40°10' N. latitude, southern Ore-  
2172 gon. Live and dead commercial fisheries were combined for northern Oregon as commercial  
2173 landings were low in this area.

2174 *Recreational*: The recreational fleets include six separate fleets, one each for the party/charter  
2175 and private/rental modes in the following areas, California north of 40°10' N. latitude, south-  
2176 ern Oregon, and northern Oregon.

2177 **Southern Model**

2178 *Commercial*: The commercial fleets include separate catches for the live and dead fish fish-  
2179 eries, as well as discards from the live-fish fishery.

2180 *Recreational*: The recreational fleets include landings from the party/charter and pri-  
2181 vate/rental modes. There are three indices of abundance: CDFW 1989-1999 CPFV onboard  
2182 observer, CDFW 2000-2014 CPFV onboard observer, MRFSS 1980-2003 CPFV dockside.

2183 *Research*: Length compositions from Jeff Abrams thesis (Abrams 2014) and the CCFRP  
2184 study.

2185 **2.4.3 Summary of data for fleets and areas**

2186 **2.4.4 Modeling software**

2187 The STAT team used Stock Synthesis 3 version 3.24u by Dr. Richard Methot at the NWFSC.  
2188 This most recent version (SS-V3.24u) was used, since it included improvements and correc-  
2189 tions to older versions.

2190 **2.4.5 Data weighting**

2191 Length composition sample sizes for all models were tuned by the “Francis method” (also  
2192 known as “TA1.8”) (Francis 2011), as implemented in the r4ss package. This approach  
2193 involves comparing the residuals in the model’s expected mean length with respect to the  
2194 observed mean length and associated uncertainty derived from the composition vectors and

their associated input sample sizes. The sample sizes are then tuned so that the observed and expected variability are consistent. After adjustment to the sample sizes, models were not re-tuned as long as the bootstrap uncertainty value around the tuning factor overlapped 1.0.

Age compositions and conditional-age-at-length (CAAL) compositions were re-weighted using the Ianelli-McAllister harmonic mean method (McAllister and Ianelli 1997). Two variations on the Francis method were also considered for the CAAL data, dependent on whether or not the vectors of age at length are considered independent within each year. Data weighting in general, and the Francis method are topics of ongoing research and there is no clear guidance on a preferred method. In the southern model, both approaches indicated that the fit was already better than expected with the input sample sizes left in place. For the central and northern models, Francis method A suggested that the CAAL sample sizes should be greatly reduced to achieve reasonable fit (effectively down weighting the CAAL data out of the northern model) while Francis method B suggested little tuning was needed.

#### 2.4.6 Priors

In the pre-STAR panel base models, the mean of the priors for Beverton-Holt steepness parameter (Dorn, M. and Thorson, J., pers. comm.) and natural mortality (Hamel 2015) were used as fixed values across the three models. The priors were applied in sensitivity analyses where these parameters were estimated.

The final base models also used the mean of the Beverton-Holt steepness prior, but fixed natural mortality at the mean of the estimated values from the northern and southern regions.

#### 2.4.7 General model specifications

Stock synthesis has a broad suite of structural options available. Where possible, the ‘default’ or most commonly used approaches are applied to this stock assessment. The assessment is sex-aggregated, including the estimation of growth curves and selectivity.

This stock assessment is divided into three independent areas, the south (California south of 40°10' N. latitude), the central (north of 40°10' N. latitude to the Oregon-Washington border), and the north (Washington state) based on latitudinal patterns in the length composition data and fits to size at age data. The time-series of landings begins during 1900, and captures the inception of the fishery, so the stock is assumed to be in equilibrium at the beginning of the modeled period.

The internal population dynamics model tracks ages 0-80, where age 80 is the ‘plus-group.’ As there is little growth occurring at age 80, the data use a plus group of age 50; there are relatively few observations in the age compositions that are greater than age 50.

All models used the posterior predictive fecundity relationship from Dick (2009).

2230 The following likelihood components are included: catch, indices, discards (south only),  
2231 discarded catch (south only), length compositions, age compositions, parameter priors, and  
2232 parameter soft bounds. See the SS technical documentation for details (Methot and Wetzel  
2233 2013).

2234 Model data, control, starter, and forecast files can be found in Appendices A-D.

#### 2235 **2.4.8 Estimated and fixed parameters**

2236 A full list of all estimated and fixed parameters is provided in Tables 36, 37, and 38. Time-  
2237 invariant, sex-aggregated growth is estimated for all modeled areas in this assessment. Re-  
2238 cruitment deviations are not estimated due to a lack of visible cohorts in either the length  
2239 or age data. In the pre-STAR models natural mortality was fixed at 0.053, the median  
2240 of the Hamel prior (Hamel 2015), and the stock-recruitment steepness is fixed at the SSC  
2241 approved steepness prior of 0.773. However, post-STAR models fix M at 0.07 for all models,  
2242 the average of the estimated M's from the northern and southern models (the central area  
2243 model was unable to estimate M). Asymptotic selectivity is generally used in the base case  
2244 models.

### 2245 **2.5 Model Selection and Evaluation**

#### 2246 **2.5.1 Key assumptions and structural choices**

2247 All structural choices for stock assessment models are likely to be important under some  
2248 circumstances. In this assessment these choices are generally made to 1) be as objective as  
2249 possible and 2) follow generally accepted methods of approaching similar models and data.  
2250 The relative effect on assessment results of each of these choices is often unknown; however  
2251 an effort is made to explore alternate choices through sensitivity analysis. Major choices in  
2252 the structuring of this stock assessment model include the independent north, central and  
2253 south area models that use disaggregated fleet structuring and mirrored selectivity for fleets  
2254 with little or no length and age composition data. All of these models fix the values for  
2255 natural mortality and stock-recruitment steepness as there is not enough information in the  
2256 data to reliably estimate these important productivity parameters. Recruitment is assumed  
2257 to be deterministic in all models, as the data do not contain sufficient information to resolve  
2258 the strength of individual year classes.

#### 2259 **2.5.2 Alternate models explored**

2260 Sensitivity analyses included a comparison of key model assumptions were based on nested  
2261 models and included asymptotic vs. domed selectivity, alternative values of M, and alter-  
2262 native fleet mirroring structure for estimating selectivity. For the area North of 40°10' N.  
2263 latitude, an alternative model in which both Central and North areas were included in a

2264 single, spatially-explicit model. However, differences in growth found between Oregon and  
2265 Washington supported independent models.

2266 **2.5.3 Convergence**

2267 Convergence testing through use of dispersed starting values often requires extreme values  
2268 to actually explore new areas of the multivariate likelihood surface. Jitter is a SS option  
2269 that generates random starting values from a normal distribution logically transformed  
2270 into each parameter's range (Methot 2015). Table 39 shows the results of running 100 jitters  
2271 for each pre-STAR base model. The northern model, which has the least amount of data  
2272 and the fewest number of estimating parameters (8), returned to the same base case solution  
2273 every time. The central model, with 14 parameters had 6% of the starting values cause  
2274 errors in the likelihood but the remaining runs returned to the base model. The southern  
2275 model, which had the most estimated parameters (16), had some jitters converge to a local  
2276 minimum with worse likelihood, but the majority returned to the base model.

2277 **2.6 Base-Model(s) Results**

2278 Base models for all three areas (northern, central, and southern) are combined sex models,  
2279 based on lack of evidence for sexually dimorphic growth in the available size-at-age data as  
2280 well as in previous studies. Key productivity parameters are fixed at measures of central ten-  
2281 dency from prior distributions endorsed by the PFMC's SSC due to the models' inability to  
2282 estimate reasonable parameter values. Specifically, steepness of the assumed Beverton-Holt  
2283 stock-recruitment relationship was fixed at 0.773. In the final base models the instantaneous  
2284 rate of annual natural mortality was fixed at  $0.07\text{yr}^{-1}$ , the average between the estimated  
2285 natural mortality from the northern and southern models. Estimated parameters in each  
2286 model vary, and are described in the area-specific results sections, below.

2287 **Northern**

2288 The northern base-case model produces reasonable estimates of growth parameters, with  
2289 China rockfish in northern Washington reaching a maximum length of 35.4 cm (Table 36,  
2290 Figure 84). The northern base-case model was able to fit the northern Washington recre-  
2291 ational index of abundance with an estimated additional standard deviation of 0.13 (Table  
2292 36). However, there are runs of years in which the model consistently either over or under  
2293 fits the data (Figure 85). The model fit to the index estimates a declining trend in the fit  
2294 between the 1980s and 1990s, followed by a flat trend through recent years.

2295 Fits to the time aggregated southern Washington recreational length distributions are poor,  
2296 where data are sparse, with the model expecting more fish sized approximately 27 cm to 34  
2297 cm and fewer fish greater than 40 cm than are present in the data (Figure 86). However, fits  
2298 to the time aggregated northern Washington recreational length distributions, the area with  
2299 most of the data and landings, are good (Figures 86 and 87). The model fits the recreational

2300 conditional age-at-length data reasonably (Figures 88 and 89). There are a few outliers,  
2301 including two 15-year-old fish in the 22 cm bin in 2005 and one 14-year-old fish in the 20 cm  
2302 bin in 2010 but there are no strong patterns in the residuals.

2303 Estimated selectivity curves for the Washington recreational southern and northern fleets  
2304 suggest different ascending width parameters, resulting in the southern fleet selecting smaller  
2305 China rockfish than the northern fleet (Figure 90). The southern fleet asymptote was unable  
2306 to be estimated so it was fixed to the estimate from the northern fleet.

## 2307 Central

2308 The central base-case model produces reasonable estimates of growth parameters, with China  
2309 rockfish in the central area reaching a length of 37.44 cm at age 30 (Table 37, Figure 84). The  
2310 central base-case model fits to the indices of abundance are generally flat to slightly declining,  
2311 with many model fits showing runs of years in which the model consistently either over or  
2312 under fits the data (Figures 91, 92, 93). Each of the central model indices of abundance except  
2313 the Oregon southern commercial live fish fishery were fit estimating additional standard  
2314 deviations of 0.15, 0.50, and 0.08 for the Oregon commercial logbook index, the Oregon  
2315 onboard recreational index, and the Oregon ORBS index, respectively (Table 37).

2316 Fits to the central model length distributions are reasonable given the small samples sizes,  
2317 particularly during the early years, and the constraints applied to selectivity parameters  
2318 (Figures 94, and 95). The model fits the Oregon southern commercial fishery best, shifts the  
2319 peak of the fitted distribution to the left for the Oregon southern recreational private/rental,  
2320 Oregon southern recreational party/charter, and Oregon northern recreational private/rental  
2321 fleets, and under fits the peak of the time aggregated length distributions for the Oregon  
2322 southern commercial live fish and Oregon northern recreational party/charter fleets. The  
2323 model fits the conditional age-at-length data from the southern Oregon commercial dead-  
2324 fish fishery poorly with clusters in the residuals and fewer observations in the age-50+ bin  
2325 than expected by the model (Figure 96). The residual patterns are less notable in the fit to  
2326 conditional age-at-length data from the southern Oregon recreational party/charter (Figure  
2327 97). For both these datasets, the largest residuals are associated with young fish at large  
2328 sizes, including commercial catch of fish aged 10 years and younger in the 35-40cm range in  
2329 2002 through 2004 and a recreational observation in 2011 in the 44 cm length bin estimated  
2330 at 10 years old. In many years the model expects more fish in the plus group (age 50) than are  
2331 actually present in the data, but years where 50+ age fish were observed, this observations  
2332 is typically larger than the expectation. The fit to the marginal age compositions from the  
2333 northern Oregon recreational fishery are reasonable given the low sample sizes of this fleet  
2334 (which is the reason it was not represented as conditioned on length) although generally more  
2335 fish in the 5-10 year old range were observed than expected by the model (Figure 98).

2336 The central model does not explicitly model discards due to low discard rates and the limited  
2337 availability of discard data. However, a discard fraction of 2.69% of the annual commercial  
2338 landings has been added to the commercial landings to account for the total removals by the  
2339 commercial fisheries.

2340 Asymptotic selectivity curves are estimated for all fleets with length compositions (Figure  
2341 99). The exceptions included the northern Oregon commercial fishery which shared the se-  
2342 lectivity curve for the southern Oregon life-fish commercial fishery, and the northern Oregon  
2343 private/rental fleet that was assumed to share the selectivity with the party/charter fleet  
2344 in this same area. Many of the recreational has estimates of peak selectivity that hit the  
2345 upper bound of 45 cm, well above the estimated asymptotic size. These parameters were  
2346 all reduced to (fixed at) the highest peak selectivity parameter among the recreational fleets  
2347 that was not hitting a bound: 39.9 cm. The ascending width parameters showed small dif-  
2348 ferences among all fleets (Table 37). The commercial selectivity parameters generally had  
2349 peak values estimated at a lower point than the recreational selectivities.

## 2350 Southern

2351 The model for the area south of 40°10' N. latitude produces reasonable values of estimated  
2352 growth parameters in the base-case model, with China rockfish in the southern management  
2353 area reaching an asymptotic length (converted from Schnute parameterization) of 31.5 cm,  
2354 with von Bertalanffy growth coefficient,  $k = 0.144$ , and a coefficient of variation of 12%  
2355 for length at age 30 (Figure 84). The southern base-case model best fit the southern area  
2356 recreational dockside index of abundance with an estimated additional standard deviation  
2357 of 0.12, and the two recreational onboard indices (1988-1999 and 2000-2014) with additional  
2358 SDs of 0.15 and 0.18, respectively (Table 38). However, in all three indices there are runs  
2359 of positive or negative residuals. The model is able to capture a decline in catch rates from  
2360 the 1980s to the late 1990s / early 2000s in the dockside recreational CPUE index (Figure  
2361 100), but slightly underestimates a declining trend in the 1988-1999 onboard observer index  
2362 (Figure 101). The model is consistent with an observed increasing trend from 2000-2012 in  
2363 the more recent onboard observer index, but was not able to capture a recent drop in catch  
2364 rates in recent years (Figure 102).

2365 Fits to the time-aggregated southern recreational private and charter boat length distribu-  
2366 tions, the fleets with most of the data and landings, are most consistent with the observed  
2367 data (Figure 103). Length data from the commercial fisheries (live-fish fishery and fish  
2368 landed dead) are fit reasonably well by the model (Figure 103).

2369 Fits to the length compositions from the central California onboard observer and CCFRP  
2370 surveys (fleets observing whole, retained plus discarded, catch) are good for the onboard  
2371 observer data (which mirrors the selectivity of the recreational charter boat fishery), but the  
2372 model a larger variance and smaller mode in time-aggregated lengths relative to the data  
2373 from the CCFRP survey (Figure 104).

2374 The model fits the conditional age-at-length data from Jeff Abrams' thesis (Abrams 2014)  
2375 reasonably well (Figure 105), particularly for years with larger sample sizes.

2376 Length-based selectivity parameters estimated in the southern base model include, for each  
2377 fleet, the size at 100% vulnerability ('peak' parameter), and the 'width' of the ascending  
2378 limb of the selectivity curve (a cumulative normal distribution, Figure 68). Peak values  
2379 ranged from 27.6 cm (commercial discards) to 35.5 cm (commercial live-fish fishery). The

2380 recreational catches represent both retained and discarded fish, the composition data in the  
2381 base model represents only retained fish. Recreational length composition data for discarded  
2382 fish are available from the onboard charter boat observer programs, and could potentially be  
2383 used to model retention and selectivity separately. The STAT was not able to attempt this  
2384 analysis for the southern model due to time constraints (see research recommendations).

2385 Discards in the pre-STAR base model were estimated in the southern area model for the  
2386 commercial live-fish fishery. This model did not fit the length composition data for the  
2387 commercial live-fish fishery well, and did not capture the increasing trend in the proportion  
2388 of discarded catch south of Cape Mendocino. During the STAR panel, the STAT adopted a  
2389 recommendation made by the panel to treat discarded commercial catch as a separate “fleet”  
2390 in Stock Synthesis, which greatly improved the fits to the discard length composition data  
2391 and greatly improved the fits to the length composition of retained catch in the commercial  
2392 live-fish fishery.

## 2393 2.7 Uncertainty and Sensitivity Analyses

2394 The base-case assessment model includes parameter uncertainty from a variety of sources,  
2395 but underestimates the considerable uncertainty in recent trend and current stock status. For  
2396 this reason, in addition to asymptotic confidence intervals (based upon the model’s analytical  
2397 estimate of the variance near the converged solution), two alternate states of nature (low  
2398 and high values of M) are presented in a decision table. Much additional exploration of  
2399 uncertainty was performed prior the STAR panel. Some of that exploration of other sources  
2400 of uncertainty is provided below. Specifically, for each pre-STAR area model, the following  
2401 sensitivity runs were performed:

- 2402 1. “Drop-one” analyses: remove single data types from the model – indices, discards,  
2403 length compositions (down-weighted by scaling Francis weights by factor of 0.25), and  
2404 age compositions.
- 2405 2. Alternative data-weighting criterion. The base model length compositions are tuned  
2406 based on the Francis method (Francis2011), as implemented in the r4ss package. An  
2407 alternative method based on the harmonic mean effective sample size (McAllister and  
2408 Ianelli 1997).
- 2409 3. Free up size at age 0 (1 run) and CV at A\_min (1 run)
- 2410 4. Fix growth at external estimate (1 run)

### 2411 Northern Model

2412 Tabular results for the northern area pre-STAR model sensitivity runs can be viewed here:  
2413 [40](#), and associated figures are here: Figures [106](#) and [107](#). The model for the northern management  
2414 area was not sensitive to dropping the index of abundance, data weighting methods,

2415 downweighting length comps (75% reduction in Francis weights, i.e. weights multiplied by  
2416 0.25). The pre-STAR models that attempted to estimate the size at age 0 and CV at Age  
2417 minimum growth parameters resulted parameters going to bounds, producing unrealistic  
2418 estimates for these parameter values. The pre-STAR model was highly sensitive to the  
2419 exclusion of age the com- position data and fixing growth the the externally estimated values.  
2420 Lack of age data and fixing growth to the external estimates produced an approximate  
2421 doubling in the estimates of the stock size and in the status of the population. Removal of  
2422 the age composition data, modeled as conditional age-at-length, impacts the scale of the pre-  
2423 STAR model, in part because the pre-STAR model is no longer able to estimate reasonable  
2424 values of growth parameters. Fixing growth to the externally estimated values is problematic  
2425 because the data lack small/young fish, resulting in high sensitivity to the k estimate.

2426 When estimated with their respective prior distributions, both steepness and natural mor-  
2427 tality are larger than the fixed values in the pre-STAR base model ( $h = 0.95$ , and  $M = 0.07$ ).  
2428 However, the higher estimate of  $M$  contradicts the observed maximum age of 83 and the  
2429 higher  $h$  estimate is inconsistent with the current understanding of rockfish productivity.

2430 Additional sensitivities conducted during the STAR panel are described in the section “Re-  
2431 sponse to the 2015 STAR Panel Requests.”

## 2432 Central Model

2433 Tabular results for the central area pre-STAR model sensitivity runs can be viewed here:  
2434 Table 41, and associated figures are here: Figures 108 and 109. The pre-STAR model for the  
2435 central management area was not sensitive to dropping the index of abundance, data weight-  
2436 ing methods, downweighting length comps (75% reduction in Francis weights, i.e. weights  
2437 multiplied by 0.25). The pre-STAR models that attempted to estimate the size at age 0 and  
2438 CV at Age minimum growth parameters resulted parameters going to bounds, producing  
2439 unrealistic estimates for these parameter values. The pre-STAR model was highly sensitive  
2440 to the exclusion of age the composition data and fixing growth the externally estimated  
2441 values. Lack of age data resulted in an inability to estimate  $R_0$ , leading to unrealistic model  
2442 results. Fixing growth to the external estimates produced an approximate doubling in the  
2443 estimates of the stock size and in the status of the population. Fixing growth to the exter-  
2444 nally estimated values is problematic because the data lack small/young fish, resulting in  
2445 high sensitivity to the k estimate.

2446 The central pre-STAR base model is unable to estimate  $M$  but when  $h$  is estimated it goes  
2447 to a value of 0.75, very close to the fixed value from the pre-STAR base model of 0.773,  
2448 indicating that the data do not contain much information about stock productivity.

2449 Additional sensitivities conducted during the STAR panel are described in the section “Re-  
2450 sponse to the 2015 STAR Panel Requests.”

## 2451 Southern Model

2452 The pre-STAR base model for the southern management area was not very sensitive to drop-  
2453 ping indices or discard data, or to downweighting length comps (75% reduction in Francis

weights, i.e. weights multiplied by 0.25). However, exclusion of age composition data significantly altered estimates of the scale and status of the population (Table 42; Figures 110 and 111). Removal of marginal age composition data and conditional age-at-length data had a dramatic effect on model results, in part because the model is no longer able to estimate credible values of growth parameters (e.g. von Bertalanffy  $k = 0.027$ ; Figure 112).

Weighting of data types (e.g. composition data vs. indices) in the pre-STAR base models was based on the method of Francis (2011), as implemented in the r4ss package. An alternative method based on the harmonic mean effective sample size (McAllister and Ianelli 1997) was applied, and results were consistent with the Francis method (Figures 113 and 114).

The pre-STAR base model fixes length at age zero at 2 cm, with a CV of 0.1. Separate attempts to estimate these parameters in the model failed, with both going to unrealistic boundaries, i.e. size at age 0 years of 10 cm, and a CV of 0.01 (results not shown). If growth is estimated external to the model and fixed at those estimates, fits to the model degrade (increased negative log likelihoods) and the stock is more depleted, with biomass in 2015 at 23% of unfished biomass, below the minimum stock size threshold (Figures 115, 116, and 117).

The southern pre-STAR base model fixed parameters that determine stock productivity (steepness and natural mortality) at point estimates derived from prior distributions (see prior distributions section for details). When estimated with their respective prior distributions, both steepness and natural mortality are larger than the fixed values in the base model ( $h = 0.92$ , and  $M = 0.1$ ). As noted in the profile likelihood analyses, the length and age composition data appear to support higher M values, but this contradicts the observed maximum age of 83. The data appear to have little information about steepness, and the estimated value is near the mode of the prior distribution (Figure 118). Higher values of steepness and natural mortality result in a smaller, less-depleted stock (Figures 119 and 120). The estimated growth curve also changes, with a lower value of  $k$  and higher asymptotic size (Figure 121).

Additional sensitivities conducted during the STAR panel are described in the section “Response to the 2015 STAR Panel Requests.”

### 2.7.1 Retrospective analysis

Retrospective analyses were conducted for each pre-STAR base model by conducting model runs that sequentially remove the last year of data over the last 5 base model years. The southern model showed very little change in estimated spawning biomass trajectory as a result of this data removal (Figure 122). The central and northern models, however, showed that each additional year of data added to the model has resulted in a higher initial spawning biomass (Figures 123 and 124). These results are consistent with the dependence of the central and northern models on more recently collected data as compared to the southern model where the catch history began earlier.

2492 **2.7.2 Likelihood profiles**

2493 **Pre-STAR base model likelihood profiles**

2494 Likelihood profiles for equilibrium recruitment ( $R_0$ ), natural mortality ( $M$ ), and steepness  
2495 ( $h$ ), were completed to investigate the uncertainty in these parameters and their influence  
2496 on the fit to different data sources. For all models, the age data had the largest influence  
2497 on the scale of the population as indicated by the data type most influenced by  $R_0$  (Figures  
2498 125, 126, and 127). In the southern model, the length and index data also had the best fit at  
2499 a similar scale, showing consistency in these data sources about the population size. In the  
2500 central model, lower  $R_0$  values caused the model to fit the length data less well but higher  
2501 values had little influence. The index data was most influential on the  $R_0$  estimates in the  
2502 northern model, where they were best fit with a higher equilibrium recruitment.

2503 Profiles over natural mortality showed length and age data best fit by high  $M$  values (greater  
2504 than 0.10) in the central and south models (Figures 128 and 129), while the value among  
2505 those in the profile with best likelihood in the northern model was  $M = 0.08$  (Figure 130).  
2506 As in the profile over  $R_0$ , the index data in the northern model showed a larger influence on  
2507  $M$  than the index data in the central and southern models.

2508 Likelihood profiles were conducted over four values for the steepness of the stock-recruit  
2509 curve ( $h = 0.3, 0.6, 0.773$ , and  $0.9$ ), where  $0.773$  is the mean of the prior distribution and  
2510 chosen as a fixed value in the three base models. These profiles indicated that for the  
2511 southern and northern models (Figures 131 and 132), length and age data were best fit by  
2512 high steepness values, with the index in the northern model also showing a better fit at  
2513 higher steepness. The central model, however, showed the best combined fit to all data  
2514 sources at an intermediate value of steepness, with an MLE estimate when the parameter  
2515 was estimated of  $h = 0.753$ , which is close to the prior mean (Figure 133). This estimate  
2516 represents a balance between the age data and steepness prior, which were best fit at higher  
2517 steepness values, and the length data, which was best fit at lower steepness values. The index  
2518 data in the central model showed less change in likelihood as a result of the steepness profile  
2519 than the other data types, but it was the only type that was best fit at an intermediate  
2520 value,  $h = 0.6$ .

2521 **Final base model likelihood profiles**

2522 Likelihood profiles over natural mortality were conducted for all of the final base models,  
2523 and sensitivities to those models (Figures 134, 135, and 136). The northern model had the  
2524 best combined fit at the estimated value of natural mortality. The southern model showed a  
2525 good fit to the estimated value of natural mortality for the index data and the priors. The  
2526 length data in the souther model indicated a better fit at a lower value of natural mortality  
2527 whereas the age data indicated the best fit towards the upper bound of the profile,  $M=0.12$ .  
2528 The central model was not able to estimate a reasonable value for natural mortality, with all  
2529 data sources indicating the best fit to the data towards the upper bound of natural mortality  
2530 in the profile.

## 2531 3 Reference Points

### 2532 Northern Model

2533 This stock assessment estimates that China rockfish in the north are well above the biomass  
2534 target. The spawning biomass of the stock declined between the 1960s and 1990s but has  
2535 largely been stable during the past few decades (Table 43; Figure 137). The estimated relative  
2536 depletion level in 2015 is 73.4% (~95% asymptotic interval:  $\pm 63.6\% - 83.2\%$ ), corresponding  
2537 to an unfished spawning output of 17.9 billion eggs (~95% asymptotic interval: 8.8 – 27.1  
2538 billion eggs) of spawning output in the base model (Table b; Figure 138). Unfished spawning  
2539 output was estimated to be 24.4 billion eggs in the base case model. The target spawning  
2540 output based on the biomass target ( $SB_{40\%}$ ) is 9.8 billion eggs, which gives a catch of 6.2  
2541 mt. Equilibrium yield at the proxy  $F_{MSY}$  harvest rate corresponding to  $SPR_{50\%}$  is 5.8 mt.  
2542 Table k shows the full suite of estimated reference points for the northern area model and  
2543 Figure 139 shows the equilibrium yield curve.

### 2544 Central Model

2545 This stock assessment estimates that central area China rockfish are just above the biomass  
2546 target (Table 44; Figure 140). The rate of spawning output decline is estimated to be  
2547 steepest during the 1980s to 1990s and has continued to decline since the 1990s at a slower  
2548 rate (Figure 141). The estimated relative depletion level in 2015 is 61.5% (~95% asymptotic  
2549 interval:  $\pm 53.8\% - 69.2\%$ ), corresponding to an unfished spawning output of 65.1 billion eggs  
2550 (~95% asymptotic interval: 51.8 – 78.4 billion eggs) of spawning output in the base model  
2551 (Table c). Unfished age 5+ biomass was estimated to be 591.5 mt in the base case model.  
2552 The target spawning output based on the biomass target ( $SB_{40\%}$ ) is 26 billion eggs, which  
2553 gives a catch of 15.7 mt. Equilibrium yield at the proxy  $F_{MSY}$  harvest rate corresponding to  
2554  $SPR_{50\%}$  is 14.5 mt. Table l shows the full suite of estimated reference points for the central  
2555 area model and Figure 142 shows the equilibrium yield curve.

### 2556 Southern Model

2557 This stock assessment estimates that China rockfish south of  $40^{\circ}10' N.$  latitude are below the  
2558 biomass target, but above the minimum stock size threshold, and have been increasing over  
2559 the last 15 years (Table 45; Figure 143). The estimated relative depletion level in 2015 is  
2560 27.9% (~95% asymptotic interval:  $\pm 21.2\% - 34.7\%$ ), corresponding to an unfished spawning  
2561 output of 66.5 billion eggs (~95% asymptotic interval: 49.6 - 83.4 billion eggs) of spawning  
2562 output in the base model (Table d). Unfished age 5+ biomass was estimated to be 768.6  
2563 mt in the base case model (Figure 144). The target spawning output based on the biomass  
2564 target ( $SB_{40\%}$ ) is 26.6 billion eggs, which gives a catch of 21.1 mt. Equilibrium yield at  
2565 the proxy  $F_{MSY}$  harvest rate corresponding to  $SPR_{50\%}$  is 19.5 mt. Table m shows the full  
2566 suite of estimated reference points for the southern area model and Figure 145 shows the  
2567 equilibrium yield curve.

## 2568 4 Harvest Projections and Decision Tables

2569 The forecasts of stock abundance and yield were developed using the final base models. The  
2570 total catches in 2015 and 2016 are set to the PFMC adopted China rockfish contribution  
2571 ACLs in the northern and central models (Table n). The southern model total catches in  
2572 2015 and 2016 are set to the average annual catch from 2012-2014. The exploitation rate for  
2573 2017 and beyond is based upon an SPR harvest rate of 50%, adjusted by the default 40-10  
2574 harvest control rule. The average of 2010-2014 catch by fleet was used to distribute catches  
2575 in forecasted years.

2576 **Northern Model** Current medium-term projections of expected China spawning biomass  
2577 from the northern base model suggests slight declines from the current levels as the stock  
2578 moves towards the current target stock size under the default harvest control rule (Table 46,  
2579 Figures 146 and 147). The stock is expected to remain above the target stock size during  
2580 the projection period, assuming stationarity in the stock-recruitment assumptions.

2581 Uncertainty in the forecasts is based upon the three states of nature agreed upon at the STAR  
2582 panel and are based on a low value of M, 0.05, and a high value, 0.09. Current medium-term  
2583 forecasts based on the alternative states of nature project that the stock, under the current  
2584 control rule as applied to the base model, will decline towards the target stock size Table  
2585 p. The current control rule under the low state of nature results in a stock decline into  
2586 the precautionary zone, while the high state of nature maintains the stock at near unfished  
2587 levels. Removing the catches resulting from the low M state of nature, assuming the base  
2588 and high values of M both maintain the stock at well above the current target stock size, as  
2589 does removing the recent average catches under all states of nature. Removing the high M  
2590 catches under the base model M and high M states of nature results in the population going  
2591 to extremely low levels during the projection period, spawning biomass and stock depletion  
2592 values are not reported for years in which the stock goes to these very low levels.

### 2593 Central Model

2594 Current medium-term projections of expected China spawning biomass from the central base  
2595 model suggests stable catches near current levels as the stock is just above the current target  
2596 stock size under the default harvest control rule (Table 47, Figures 146 and 147). The stock is  
2597 expected to remain just above the target stock size, increasing slightly, during the projection  
2598 period, assuming stationarity in the stock-recruitment assumptions.

2599 Uncertainty in the forecasts is based upon the three states of nature agreed upon at the STAR  
2600 panel and are based on a low value of M, 0.05, and a high value, 0.09. Current medium-  
2601 term forecasts based on the alternative states of nature project that the stock, under the  
2602 current control rule as applied to the base model, will decline towards the target stock size  
2603 Table q. The current control rule under the low state of nature results in a stock in the  
2604 precautionary zone, while the high state of nature maintains the stock increasing from 40%  
2605 to 50% depletion from 2017 - 2026. Removing the catches resulting from the low M state of  
2606 nature, assuming the base and high values of M both maintain the stock at well above the

2607 current target stock size. Removing the high M catches under the base model M and low M  
2608 states of nature results in the population going to extremely low levels during the projection  
2609 period. Removing average catches under the base M and high M states of nature result in  
2610 the stock remaining above the current target stock size, and an ending depletion of 37% in  
2611 2026 for the low M state of nature.

## 2612 Southern Model

2613 Assuming that catches in 2015 and 2016 equal recent average catch, and that catches be-  
2614 ginning in 2017 follow the default ACL harvest control rule, projections of expected China  
2615 spawning output from the southern base model suggest the stock will be at roughly 30% of  
2616 unfished spawning output in 2017, and increase to 38% by 2026 (Table 48, Figures 146 and  
2617 147). The stock is expected to remain below the target stock size (40% of unfished spawning  
2618 output) in the base model and “low M” states of nature through 2026, and to exceed target  
2619 size in the “high M” scenario, assuming stationarity in the stock-recruitment assumptions.

2620 Uncertainty in the forecasts is based upon the three states of nature agreed upon at the STAR  
2621 panel: a low value of M, 0.05, the base model value, M=0.07, and a high value, M=0.09.  
2622 Stock status under the alternative states of nature ranges from an overfished state in 2017  
2623 for the low-M scenario (21% of unfished spawning output) to a stock at target biomass (40%  
2624 of unfished) in the high-M scenario (Table r). Annual catches based on the low-M state of  
2625 nature increase from 5 to 10 mt over the projection period, and result in an increasing stock  
2626 under all three states of nature. Catches derived from the base model increase from 11 mt  
2627 in 2017 to 15 mt in 2026, and also produce increasing trends (at different rates) in spawning  
2628 output under all three states of nature. Catches under the high-M state of nature produce  
2629 very little change in spawning output over the projection period for all three states of nature.

## 2630 5 Regional Management Considerations

2631 China rockfish is currently managed as part of the nearshore rockfish stock complex, and  
2632 as such, does not have a species-specific ACL. The complex is divided into northern and  
2633 southern components around the PFMC management line at 40°10' N. latitude (near Cape  
2634 Mendocino, California). This management boundary is consistent with observed spatial pat-  
2635 terns in the data (e.g. length compositions, size at age, commercial discard rates), and OFL  
2636 estimates for the northern and southern management regions can be calculated directly from  
2637 the base model runs and projections (southern model = OFL for southern nearshore rockfish  
2638 complex, central + northern models = OFL for northern nearshore rockfish complex).

## 2639 6 Research Needs

- 2640 1. The number of hours fished in Washington should be recorded for each dockside sample  
2641 (vessel) so that future CPUE can be measured as angler hours rather than just number

- 2642 of anglers per trip. This will allow for a more accurate calculation of effort.
- 2643 2. The number of hours fished in Oregon should be recorded for each dockside sample  
2644 (vessel), instead of the number of the start and end times of the entire trip. This will  
2645 allow for a more accurate calculation of effort.
- 2646 3. Compare the habitat-based methods used to subset data for the onboard observer  
2647 indices to Stephens-MacCall and other filtering methods.
- 2648 4. Explore the sensitivity of Stephens-MacCall when the target species is “rare” or not  
2649 common encountered in the data samples.
- 2650 5. A standardized fishery independent survey sampling nearshore rockfish in all three  
2651 states would provide a more reliable index of abundance than the indices developed  
2652 from catch rates in recreational and commercial fisheries. However, information value  
2653 of such surveys would depend on the consistency in methods over time and space and  
2654 would require many years of sampling before an informative index could be obtained.
- 2655 6. A coastwide evaluation of genetic structure of China rockfish is a research priority.  
2656 Genetic samples should be collected at sites spaced regularly along the coast throughout  
2657 the range of the species to estimate genetic differences at multiple spatial scales (i.e.,  
2658 isolation by distance).
- 2659 7. Difficulties were encountered when attempting to reconstruct historical recreational  
2660 catches at smaller spatial scales, and in distinguishing between landings from the pri-  
2661 vate and charter vessels. Improved methods are needed to allocate reconstructed recre-  
2662ational catches to sub-state regions within each fishing mode.
- 2663 8. There was insufficient time during the STAR Panel review to fully review the abun-  
2664 dance indices used in the China rockfish assessments. Consideration should be given to  
2665 scheduling a data workshop prior to STAR Panel review for review of assessment input  
2666 data and standardization procedures for indices, potentially for all species scheduled  
2667 for assessment. The nearshore data workshop, held earlier this year, was a step in this  
2668 direction, but that meeting did not deal with the modeling part of index development.
- 2669 9. The Marine Recreational Fisheries Statistics Survey (MRFSS) index in Oregon was  
2670 excluded from the assessment model because it was learned that multiple intercept  
2671 interviews were done for a single trip. Evaluate whether database manipulations or  
2672 some other approach can resolve this issue and allow these data to be used in the  
2673 assessment.
- 2674 10. Many of the indices used in the China rockfish assessment model used the Stephens-  
2675 MacCall (2004) approach to subset the CPUE data. Research is need to evaluate  
2676 the performance of the method when there are changes in management restrictions  
2677 and in relative abundance of different species. Examination of the characteristics of

2678 trips retained/removed should be a routine part of index standardization, such as an  
2679 evaluation of whether there are time trends in the proportion of discarded trips.

- 2680 11. Fishery-dependent CPUE indices are likely to be the only trend information for many  
2681 nearshore species for the foreseeable future. Indices from a multi-species hook-and-line  
2682 fishery may be influenced by regulatory changes, such as bag limits, and by interactions  
2683 with other species (e.g. black rockfish) due to hook competition. It may be possible  
2684 to address many of these concerns if a multi-species approach is used to develop the  
2685 indices, allowing potential interactions and common forcing to be evaluated.
- 2686 12. Consider the development of a fishery-independent survey for nearshore stocks. As  
2687 the current base model structure has no direct fishery-independent measure of stock  
2688 trends, any work to commence collection of such a measure for nearshore rockfish, or  
2689 use of existing data to derive such an index would greatly assist with this assessment.
- 2690 13. Basic life history research may help to resolve assessment uncertainties regarding ap-  
2691 propriate values for natural mortality and steepness.
- 2692 14. Examine length composition data of discarded fish from recreational onboard observer  
2693 programs in California and Oregon. Consider modeling discarded catch using selec-  
2694 tivity and retention functions in Stock Synthesis rather than combining retained and  
2695 discarded catch and assuming they have identical size compositions. Another option  
2696 would be to model discarded recreational catch as a separate fleet, similar to the way  
2697 commercial discards were treated in the southern model.
- 2698 15. Ageing data were influential in the China rockfish stock assessments. Collection and  
2699 ageing of China rockfish otoliths should continue. Samples from younger fish not  
2700 typically selected by the fishery are needed to better define the growth curve.
- 2701 16. Consider evaluating depletion estimators of abundance using within season CPUE  
2702 indices. This approach would require information on total removals on a reef-by-reef  
2703 basis.
- 2704 17. The extensive use of habitat information in index development is a strength of the  
2705 China rockfish assessment. Consideration should be given to how to further incorporate  
2706 habitat data into the assessment of nearshore species. The most immediate need seems  
2707 to be to increase the resolution of habitat maps for waters off Oregon and Washington,  
2708 and standardization of habitat data format among states.
- 2709 18. Although all the current models for China rockfish estimated implausibly large recruit-  
2710 ment deviations when allowed to do so, particularly early in the modeled time period,  
2711 further exploration of available options in stock synthesis could produce acceptable  
2712 results. In addition, this work may provide guidance on any additional options that could  
2713 be added to stock synthesis to better handle this situation. For example, assuming dif-  
2714 ferent levels autocorrelation in the stock-recruit relationship for data-moderate stocks  
2715 may help curb the tendency to estimate extreme recruitment with sparse datasets.

2716     19. Research is needed on data-weighting methods in stock assessments. In particular,  
2717       a standard approach for conditional age-at-length data is needed. The Center for  
2718       the Advancement of Population Assessment Methodology (CAPAM) data weighting  
2719       workshop, scheduled for later this year, should make important progress on this research  
2720       need.

## 2721     7 Acknowledgments

2722     We gratefully acknowledge input and review from the STAR panel including Martin Dorn  
2723     (Alaska Fisheries Science Center, NMFS, NOAA), Neil Klaer (Commonwealth Scientific and  
2724     Industrial Research Organization), Noel Cadigan (Memorial University of Newfoundland),  
2725     and Paul Nitschke (Northeast Fisheries Science Center, NMFS, NOAA). We also thank  
2726     John DeVore, John Budrick, and Gerry Richter for consultation during the STAR panel.  
2727     Patrick McDonald and the team of agers at CAP for reading countless China otoliths and  
2728     providing results that were critical to all three assessment models. We thank Alison Whitman  
2729     and Linda ZumBrunnen at the Oregon Department of Fish and Wildlife for providing and  
2730     error checking data for the onboard observer program. We are thankful to Jeff Abrams for  
2731     providing the age and length data, including the otolith library, from his thesis at Humboldt  
2732     State University. Jeff's data were critical for modelling growth in the southern assessment.  
2733     We thank Connie Ryan, Deb Wilson-Vandenberg, Paul Reilly, Bob Leos, Meisha Key, and  
2734     Jeanne Rimpo at the California Department of Fish and Wildlife for providing data from the  
2735     onboard observer program, answering many, many questions regarding all California data,  
2736     and reviewing the indices and catches during the data preparation process. We thank Nick  
2737     Grunloh for conducting the analysis to impute the missing number of observed anglers from  
2738     the earlier CA onboard observer program data and Rebecca Miller for compiling and assisting  
2739     in analyzing all of the reef and GIS data used for the onboard observer surveys. We thank  
2740     Kayleigh Somers who provided WCGOP data for the observer program that allowed us to  
2741     model the commercial discards as a fleet in the southern model. We thank Don Pearson for  
2742     providing California's commercial catch data and providing advice on growth models. We  
2743     also thank John Field and Owen Hamel for providing comments and edits to the assessment.

Table 3: Estimated discarded and retained China rockfish in the Nearshore Fixed-gear Fishery provided by the West Coast Groundfish Observer Program (WCGOP). For the area South of  $40^{\circ}10'$ , where discards are higher, bootstrapping was used to estimate a coefficient of variation (CV) of the total discard amount. The mortality of discarded China rockfish is estimated by WCGOP as a function of the fishing depth which varies by year. The average mortality fraction south of  $40^{\circ}10'$  across all years was 59%.

Year	Area	Estimated total discard (mt)	CV of total discard	Estimated dead discard (mt)	Estimated mortality fraction	Estimated landings (mt)	Estimated dead discard + landings	Ratio of dead discard:total dead
2003	N of $40^{\circ}10'$	0.54	-	0.25	47%	10.62	10.87	2%
2004	N of $40^{\circ}10'$	0.54	-	0.24	45%	7.28	7.52	3%
2005	N of $40^{\circ}10'$	0.38	-	0.17	45%	4.56	4.73	4%
2006	N of $40^{\circ}10'$	0.47	-	0.21	44%	5.62	5.83	4%
2007	N of $40^{\circ}10'$	0.20	-	0.08	43%	7.99	8.08	1%
2008	N of $40^{\circ}10'$	1.02	-	0.42	41%	9.40	9.81	4%

2012	S of $40^{\circ}10'$	2.73	82%	1.81	66%	1.44	3.25	56%
2013	S of $40^{\circ}10'$	1.61	53%	1.28	79%	1.20	2.47	52%

Table 4: Total number of observed trips associated with catch of China rockfish and trips with observed discards of China rockfish aggregated by  $2^\circ$  latitude bins. Range of years is 2003-2013 North of  $40^\circ 10'$  and 2004 2013 to the south. Note: No observed catch of China rockfish occurred between  $40^\circ$  and  $40^\circ 10'$ .

Latitude range	Trips observed	Trips with discards	Percent with discards
$44^\circ - 46^\circ$	46	10	22%
$42^\circ - 44^\circ$	875	324	37%
$40^\circ - 42^\circ$	144	13	9%
$38^\circ - 40^\circ$	55	45	82%
$36^\circ - 38^\circ$	146	133	91%
$34^\circ - 36^\circ$	26	26	100%

Table 9: Commercial logbook filtering criteria and resulting sample sizes used for China rockfish. Bold value indicates the final trip-level sample size used for delta-GLM analysis.

Filter	Criteria	Sample size	Level
Full data set	All data	26592	Set
Gear type	Hook and line only	22735	Set
Port	Port Orford/Gold Beach/Brookings	17100	Set
Depth	Valid set starting depth ( $\leq$ 30 fm; 54.9 m)	15663	Set
Hooks	Valid hook count (1 - 100)	16	Set
Hours	Valid hours fishing (0.1 - 20)	15180	Set
People	Valid number of fishers onboard ( $\geq$ 1)	14976	Set
Nearshore	Nearshore endorsed vessel only	13262	Set
Endorsed			
Vessel	Completed at least one set in all 10 years (2004 - 2013)	3823	Set
Trip	Aggregate multi-set trip to trip level	3575	Trip

Table 10: Abundance indices for China rockfish based on least square means from the delta-GLM model and associated standard errors from the final subset of Oregon commercial nearshore logbook submissions.

Year	Index	Log-scale SE
2004	0.0364	0.2112
2005	0.0281	0.1918
2006	0.0323	0.1997
2007	0.0382	0.2127
2008	0.0429	0.2038
2009	0.0264	0.2066
2010	0.0244	0.2536
2011	0.0395	0.2026
2012	0.0320	0.2063
2013	0.0180	0.2283

Table 11: WDFW recreational dockside data sample sizes at each data filtering step. The bold value indicates the final sample size used for delta-GLM analysis.

Filter	Criteria	Sample size with Stephens- MacCall filter	Sample size with Stephen-MacCall filter, retaining all positive observations	Sample size without Stephens- MacCall filter
Full data set	All data	736271		
Trip type	Retain only bottomfish trips	109619		
Punch Card Areas	Remove non-rockfish areas (0,5,20,42,51,55,99 (1981-1989); 0,5,6,20,41,42,51,53:56, 61 (1990-2014))	107762		
Boat Type	Remove shore-based trips	106063		
Boat Type	Remove records with missing values	106052		
Remove NAs	1980-1989 Anglers	106026		
Stephens-MacCall	Remove trips not in China habitat	12819	20608	-
Months	Remove months with little to no data (3,10)	12755	20518	104615
Sampling Area	Remove area 52, very few records	12738	20499	102267
Area	Retain only area 4	<b>10428</b>	<b>16193</b>	<b>54285</b>

Table 12: AIC values for each model using the data with Stephens-MacCall filtering for the Washington dockside index.

Model	Binomial	Lognormal
Year	14279.1	9990.2

Table 20: Sample sizes at each data filtering step for the Oregon Recreational Boat Survey data. The bold value indicates the final sample size used for delta-GLM analysis.

Filter	Criteria	Sample size (no. of trips)
Full data set	Charter boat trips from Oregon (statewide)	36752
Highliners	Retain vessels with 20+ trips;(13% of vessels made 89% of trips)	32394
Missing Effort	Delete records with TripHours=NULL	32387
Remove Multi-day	Delete trips with TripHours>12	31247
No tuna or dive trips	Drop TripType=(T or D); no China caught on tuna trips; CPUE not comparable for dive trips	30665
Extreme counter-indicators	Drop trips with common species that never co-occur with China (Blue shark, white sturgeon, steelhead and albacore)	30004
Delete catch = NA	Delete 3 trips with catch=NA	30001
Pelagic Rockfish Target	Delete trips in which >99% of catch is pelagic rockfish (silvergray, widow, yellowtail, black, blue)	28215
Stephens-MacCall	Retain all positive China trips, plus False Positives (trips predicted to be in China habitat, but with no China retained)	<b>6232</b>

Table 21: Number of trips by year and subregion in the Oregon Recreational Boat Survey (ORBS) charter boat index. Southern Oregon is defined as ports south of Florence. Northern Oregon includes the port of Florence and all ports to the OR-WA border.

Year	Southern Oregon	Northern Oregon

10299 **Appendix E. Observed Angler Prediction**

10300 The 1987-1998 CDFW onboard observer program did not record the number of anglers at a  
10301 fishing stop from 4/22/87 until 7/9/92. The goal of this analysis is to impute the number of  
10302 observed anglers in the initial period of the sampling program from the number of observed  
10303 anglers and onboard anglers from the later years of the program.

10304 The number of observed anglers at a fishing stop is a subset of the number of total number of  
10305 anglers onboard the vessel (paid plus free anglers); a quantity which is consistently recorded  
10306 throughout the entire dataset. We explored the using the total number of observed anglers  
10307 onboard the vessel in the following analyses, but it was not recorded in a consitent manner  
10308 through time, e.g., recorded as the maximum number of anglers observed at a fishing stop  
10309 during the trip, a sum of the observed anglers at each fishing stop, or the average number  
10310 of observed anglers at all fishings stops, etc.

10311 We explored a binomial regression model to predict the mean number of observed anglers at  
10312 a fishing stop from the number of total anglers, in the initial period of the data. Binomial  
10313 regression models of this general form were considered in this analysis, as well as a sensitivity  
10314 analysis among the other potential covariates available in the dataset. Among the potential  
10315 predictor variables in this study, effects related to the interviewer, and trip date were con-  
10316 sidered for inclusion in the final model by pairwise comparison of fitted model AIC values  
10317 as well as analysis of parameter significance.

10318 Effects related to interviewer were found to be very significant, although due to the high  
10319 turn-over rate of the interviewers in these data, interviewer specific effects are not useful for  
10320 prediction here. However, the total number of interviewers onboard the vessel (one or two  
10321 interviewers) was found to be strongly significant and was included in the final models as a  
10322 categorical effect.

10323 For imputing the observed number of observed anglers for the early period of the dataset  
10324 it is important to motivate an assumption of stationarity in the number of observed ang-  
10325 glers through time. Thus trip date was considered for inclusion in the model to check for  
10326 any possibility significance through time. Firstly, date was considered for inclusion in the  
10327 model as a discrete time variable; secondly, a separate model was tested using only year as  
10328 categorical variable to consider any temporal patterns. Given the number of total anglers,  
10329 neither of the models considering temporal effects were able demonstrate that the number  
10330 of observed anglers varied significantly through time. All models which included temporal  
10331 effects produced higher overall AIC values, thus supporting the assumption of stationarity  
10332 in time.

10333 Log Model:

$$y_{ij} \sim \beta_{0j} + \beta_{1j} \log(x_{ij}) + \epsilon_{ij} \quad \epsilon_{ij} \sim N(0, \sigma_j) \quad (1)$$

10334 Binomial Log Model:

**Log Model: AIC=64636.72, MSE=5.13**

Figure E1: The number of observed anglers plotted as a function of the number of total anglers. The log-normal mean curves are plotted on the scale of the data, and colored to indicate if the data was collected in the presence of one or two interviewers. Additionally, a total anglers rug plot is included to show the total angler data for which the number of observed anglers needs to be imputed.

$$y_{ij} \sim B\left( N_{ij}, \text{ logit}\left(\beta_{0j} + \beta_{1j} \log(x_{ij})\right) \right) \quad (2)$$

	totAng	totAng + intNum	log(totAng) + intNum
Normal	67387.29	65317.02	64636.72
Binomial	66099.40	63753.06	62498.83

10335 The log model considers a typical normal linear model for each interviewer level, except it  
 10336 uses the log of the number of total anglers as a predictor rather than the raw numbers of  
 10337 total anglers. The log model has several nice features for prediction in this case. Firstly by  
 10338 regressing on the log of the total anglers it improves the correlation and relative homoscedas-  
 10339 ticity of the joint data and improves the accuracy of sensitivity analysis by improving the  
 10340 standard error estimates for each parameter. Secondly the log transformation introduces the  
 10341 expected mean prediction shape, by emphasizing order of magnitude differences in the total  
 10342 number of anglers. The binomial log model considers the observed angler counts as indepen-  
 10343 dent draws from a binomial given the know number of total anglers. The log transformation  
 10344 in the binomial case is justified over the traditional binomial `glm` for similar reasons as the  
 10345 normal log model, as well as simple AIC support of the transformation. All models and  
 10346 model selection criterion were computed using the standard `glm` function in the R software  
 10347 environment for statistical computing (R Development Core Team 2013).

10348 The binomial log model was chosen for its low AIC value and reasonable mean predictions.  
 10349 Untransformed binomial models were considered, however they produce unreasonable ob-  
 10350 served angler predictions associated with the high numbers of total anglers. The log trans-  
 10351 formed Normal model provides mostly reasonable predictions, but is not supported by AIC  
 10352 when compared to the binomial models. Additionally transforms of Normal likelihood mod-  
 10353 els have no distributional way of producing observed angler predictions which do not exceed  
 10354 the total number of anglers. If a Normal likelihood model were to gather AIC support,  
 10355 predictions may require truncation. These data contain considerable noise, likely due to  
 10356 the high interviewer turnover rate, which would most effectively be modeled by including  
 10357 appropriate additional predictors to control for these effects. At this point no additional  
 10358 predictors from this dataset were considered to be both sensitive and appropriate for use  
 10359 with prediction in this case.

**Binomial Log Model: AIC=62498.83, MSE=5.14**

Figure E2: The number of observed anglers plotted as a function of the number of total anglers. The binomial mean curves are plotted on the scale of the data, and colored to indicate if the data was collected in the presence of one or two interviewers. Additionally, a total anglers rug plot is included to show the total angler data for which the number of observed anglers needs to be imputed.

10360 **Appendix F. Reef Delineation and Drift Selection**  
10361 **Methodologies**

10362 **Reef Delineation** We identified reefs as potential habitat for China rockfish in California,  
10363 Oregon and Washington using a variety of newly available spatial data sources, including 2,  
10364 3 and 5 m bathymetry, substrate, lithology and Habitat Suitability geodatabases. Available  
10365 data sources varied by latitude. To delineate reefs from Point Conception to the Oregon  
10366 border we used a 2 m binary raster layer (3 m for Cordell Bank) for substrate, where 1 =  
10367 rough, and 0 = smooth habitat (California Seafloor Mapping Project “Tier 2” GIS Products,  
10368 accessed 03.18.2013, data available from: <http://seafloor.ottrelabs.org/index.html>). Rough  
10369 and smooth substrate was identified by CSMP using 2 rugosity indices based upon bathymetric  
10370 data, surface:planar area (SA:PA), and vector ruggedness measure (VRM). We considered  
10371 areas identified as ‘rough’ as reef habitat. For reefs named Asilomar, Cypress Point, Por-  
10372 tuguese Ledge, and Point Joe only a portion of the reefs were mapped at the 2 m resolution,  
10373 therefore to identify the remaining reef, we used either a 5 m resolution VRM dataset, where  
10374 the VRM cutoff was greater than 0.001 (Young et al. 2010). For all reefs derived from either  
10375 2 m, 3 m or 5 m resolution, we applied a 5 m buffer around each reef habitat for potential  
10376 error in positional accuracy and all reefs with an area greater than or equal to 100 m<sup>2</sup> were  
10377 included. We identified seven reefs outside of the 2 m layer that contained a significant  
10378 number of CPFV points, which we decided to include in the indices. Big Reef, Blunts Reef,  
10379 Isle of St. James, Point Sur Deep, Sandhill Ledge, portions of San Gregario and Soap Bank  
10380 reefs were located just outside of 2 m, 3 m and 5 m ‘footprint’, therefore for these reefs we  
10381 used the 2005 Habitat Suitability Probability (HSP) geodatabase for China rockfish (NMFS  
10382 2005). The HSP is a modeled output from Essential Fish Habitat geodatabase and is based  
10383 upon habitat data, depth, and location, where input data are NMFS trawl datasets. In order  
10384 to identify reef habitats from the Oregon border to Washington, we used a lithology shapefile  
10385 (Goldfinger et al. 2014) that was based upon multiple seafloor mapping surveys including  
10386 multibeam and sidescan sonar, sediment grab and core samples, and images. Seafloor types  
10387 were classified according to established classification schemes (Greene et al. 1999). We con-  
10388 sidered the following lithology types as ‘reef habitat:’ Boulder, cobble, cobble mix, hard,  
10389 rock, and rock mix. All spatial data was projected to NAD 1983 UTM Zone 10.

10390 Reef systems were grouped and stratified by depth at a spatial scale biologically mean-  
10391 ful to China rockfish. China rockfish are typically sedentary and have high site fidelity,  
10392 therefore we grouped reefs in consideration of how a China rockfish would experience its sur-  
10393 roundings. Lea (1999) recaptured China rockfish in the same general location as where they  
10394 were released, however a few individuals of other rockfish species (copper (*Sebastodes caurinus*),  
10395 gopher (*Sebastodes carnatus*), olive (*Sebastodes serranoides*) and yellowtail (*Sebastodes flavidus*))  
10396 demonstrated movement up to 1.5 nautical miles (about 2,700 m), but all were captured  
10397 within the same reef system. In the Puget Sound copper, brown and quillback were found  
10398 to have a home range less than 30m<sup>2</sup> in high relief rocky areas (Matthews 1990). In other  
10399 rockfish movement studies, China rockfish were tagged but never recaptured, or there was a

sample size of 1 (Hannah and Rankin 2011), Hannah 2012). Using this limited information, we considered that China rockfish would swim no more than 200 m over smooth, sand, or muddy habitat to a neighboring reef, therefore if a reef was greater than ~200 m from rocky reef habitat it was considered a different reef system. If a reef system has contiguous habitat (no channels greater than 200 m) it remained intact, no matter how large the reef (Figures F1 and F2). A small number of reefs were merged into ‘super reefs’ to accommodate 1980s-1990s CDFW location codes that overlapped multiple reefs []. Reef areas were calculated using the zonal stats tool in ArcGIS, stratified by the depth bins 0-19 m, 20-39 m, 40-59 m, 60-79 m, 80-99 m and greater than 100 m using the CSMP depth raster (2 m, 3 m or 5 m resolution). To get depths for those reefs outside the CSMP ‘footprint’ we used the NOAA Coastal Relief Model raster dataset (90 m) for California, and 100 m digital elevation model (DEM) bathymetry from the Active Tectonics and Seafloor Mapping Lab for Oregon.

Figure F1: Map of the reefs near the Monterey peninsula in CA (a) and overlaid with the fishing location codes from the CDFW 1987-1998 onboard observer program. All fishing locations follow the confidentiality guidelines and were fished by at least three vessels during the study. Note that the size of the fishing location points does not reflect the area fished.

Figure F2: Example of the reefs in Oregon.

10412 Regions were designated to gain appropriate sample sizes needed for modelling. For Oregon,  
 10413 region differences north and south of Florence were explored. In California, 12 regions north  
 10414 of Pt. Conception were defined as follows:

- 10415 Region 1: Pt. Conception to Pt. Arguello
- 10416 Region 2: Purisima Point to Pt. Sal
- 10417 Region 3: San Luis Obispo Bay to Mill Creek ( $39.959^{\circ}$  N)
- 10418 Region 4: Lopez Point to Monterey Peninsula
- 10419 Region 5: Moss Landing to San Francisco Bay
- 10420 Region 6: Farallon Islands
- 10421 Region 7: Point Bonita to Drakes Bay
- 10422 Region 8: Point Reyes to Point Arena
- 10423 Region 9: Point Arena to south of Ten Mile River
- 10424 Region 10: north of Ten Mile River to Cape Mendocino ( $40.16667^{\circ}$  N)
- 10425 Region 11: Cape Mendocino to Eel River
- 10426 Region 12: Trinidad Head to CA/OR border

10427 **CPFV drift selection** During the 1987-1998 CDFW onboard observer program, fishing  
 10428 location was recorded as one of 459 location codes. When available, the observer also recorded  
 10429 coordinates, either latitude/longitude or Loran. The SWFSC converted all Loran coordinates  
 10430 to latitude/longitude. Using the fishing stops with available coordinates, we assigned a  
 10431 fishing location code to a reef. A handful of fishing location codes were obviously not  
 10432 associated with a reef, or a reef as identified in the above methods, and were not selected in  
 10433 the final dataset. If the coordinates spanned two reefs and we were unable to tell which reef

10434 was consistently fished for a given location code, we created aggregated the reefs. This most  
10435 commonly occurred around the Monterey Bay peninsula. This was necessary as two-thirds  
10436 of the fishing stops encountering China rockfish had no recorded coordinates and allowed  
10437 us to retain all fishing location data. Therefore, for the 1987-1998 CDFW data, any fishing  
10438 location that was assigned to a reef was included in the analyses as one of the filters applied  
10439 to the data.

10440 For each CPFV location in the California 1999-2014 and Oregon 2001-2014 data we calcu-  
10441 lated depth, nearest reef, distance from reef, nearest MPA, distance from MPA using ArcGIS.  
10442 Geoprocessing steps used were ‘near’ and ‘extract values to points.’ For consistency across  
10443 databases, we used the starting location of the drift to determine if the drift was targeting  
10444 fish associated with a reef. Drifts that had a distance of 0 m, i.e., were fishing directly on the  
10445 reef, were included in analyses. Recognizing that some drifts begin adjacent to a reef with  
10446 the intention of drifting on to the reef, as well as the fact that the starting location may not  
10447 be recorded at the very start of a drift, we devised a method for including drifts within a  
10448 certain distance of a reef.

10449 We compiled a list of rockfish species that are strictly reef associated (black and yellow rock-  
10450 fish (*Sebastodes chrysomelas*), canary rockfish (*Sebastodes pinniger*), China rockfish (*Sebastodes*  
10451 *nebulosus*), cowcod (*Sebastodes levis*), flag rockfish (*Sebastodes rubrivinctus*), gopher rockfish  
10452 (*Sebastodes carnatus*), grass rockfish (*Sebastodes rastrelliger*), greenblotched rockfish (*Sebastodes*  
10453 *rosenblatti*), kelp rockfish (*Sebastodes atrovirens*), quillback rockfish (*Sebastodes maliger*), rosy  
10454 rockfish (*Sebastodes rosaceus*), starry rockfish (*Sebastodes constellatus*), Treefish (*Sebastodes serri-*  
10455 *ceps*), vermillion rockfish (*Sebastodes miniatus*), yelloweye rockfish (*Sebastodes ruberrimus*)) (per-  
10456 sonal communication John Field and Tom Laidig, NMFS SWFSC). Using drifts that were  
10457 greater than 0m from a reef and encountered one at least one of the fifteen species listed  
10458 above, we calculated the depth for which 75% of the drifts were included. For Oregon this  
10459 was 83 m, and for California it was 34 m for drifts within the ‘footprint’ and 141 m for drifts  
10460 outside the ‘footprint.’ Any drift (with or without catch) greater than 83 m from a reef was  
10461 excluded from the analyses.

## **10462 Appendix G. Commercial Regulations Histories**

### **10463 Federal waters**

**10464** For a list of the commercial regulations in federal waters see the [Commercial Regulations Home Page](#), which is housed in the CALCOM database.

### **10466 Washington**

**10467** The following commercial regulations pertain to China rockfish species in Washington and  
**10468** were provided by the Washington Department of Fish and Wildlife.

### **10469 2008**

**10470** The groundfish trawl fishery was closed in Washington from the seaward RCA boundary  
**10471** to the shore north of 48°10' N latitude to address increased encounters with yelloweye  
**10472** and canary rockfish

### **10473 2002**

**10474** Non-Trawl RCA closed from shore to 100 fm north of 46°16' N latitude

### **10475 1995**

**10476** Commercial hook-and-line fishing in state waters (0-3 miles) was closed to preserve  
**10477** recreational fishing opportunities and avoid localized depletion; trawlers included in  
**10478** 1999

### **10479 1992**

**10480** Commercial hook-and-line limits reduced to 100 lbs north of Cape Alava and from  
**10481** Destruction Island to Leadbetter Pt.

### **10482 Oregon**

**10483** The following commercial regulations pertain to China rockfish in Oregon and were provided  
**10484** by the Oregon Department of Fish and Wildlife.

**10485** China rockfish are managed in the Other Nearshore Rockfish complex

**10486** **Harvest cap:** Total amount in regulation allowed to be impacted in a fishery (for a given  
**10487** season) including both discard mortality and landed catch mortality. Prior to 2007 this term  
**10488** was synonymous with “landing cap.”

**10489** **Landing cap:** Total amount in regulation allowed to be landed in a fishery (for a given  
**10490** season). Includes only landed catch mortality (known as a harvest cap before 2007).

### **10491 Incidental Catch Limits in Other Fisheries (established in 2004)**

**10492** **Non-permitted vessels:** 15 lbs per day of black rockfish, blue rockfish, and nearshore fish,  
**10493** combined, for no more than one landing per day. These species must make-up 25% or less  
**10494** of landed poundage, and must be taken with gear legal in the permitted fishery.

10495 **Groundfish trawl fishery:** Vessels may land no more than 1,000 lbs of dead black rockfish,  
10496 blue rockfish, and nearshore fish combined per calendar year if these species make-up 25%  
10497 or less of landing.

10498 **Non-profit aquaria or vessels contracted by non-profit aquaria** may land black  
10499 rockfish, blue rockfish, and nearshore fish for purposes of display or for conducting research  
10500 on these species.

10501 **Regulations History**

10502 A minimum size limit of 12 inches (measured from the tip of the snout to the extreme end  
10503 of the tail) was implemented for China rockfish in 2000. A sorting requirement for China  
10504 rockfish was implemented in 2003.

10505 **2014**

10506 Other Nearshore Rockfish landing cap: 14.3 mt

10507 Other Nearshore Rockfish Period Limits: All Periods 700 lbs

10508 Rockfish Conservation Area: fishing restricted to inside 30 fm

10509 **2013**

10510 Other Nearshore Rockfish landing cap: 14.3 mt (excluding tiger and vermillion rock-  
10511 fishes)

10512 Other Nearshore Rockfish Period Limits: All Periods 700 lbs

10513 Legal Gear Types: hook-and-line (including pole and line, troll, longline, and stick  
10514 gear) and pot gear (max 35 pots) if a Developmental Fisheries permit for Nearshore  
10515 species using pot gear was issued in 2003

10516 Rockfish Conservation Area: fishing restricted to inside 30 fm

10517 **2012**

10518 Other Nearshore Rockfish landing cap: 14.3 mt (excluding tiger and vermillion rock-  
10519 fishes)

10520 Other Nearshore Rockfish Period Limits: All Periods 700 lbs

10521 Rockfish Conservation Area: fishing restricted to inside 30 fm north of 43° N, restricted  
10522 to inside 20 fm from 42° – 43° N

10523 **2011**

10524 Other Nearshore Rockfish landing cap: 14.3 mt (excluding tiger and vermillion rock-  
10525 fishes)

10526 Other Nearshore Rockfish Period Limits: All Periods 700 lbs

10527 Rockfish Conservation Area: fishing restricted to inside 30 fm north of 43° N, restricted  
10528 to inside 20 fm from 42° – 43° N

- 10529 **2010**
- 10530 Other Nearshore Rockfish landing cap: 14.3 mt (excluding tiger and vermillion rock-fishes)
- 10531
- 10532 Other Nearshore Rockfish Period Limits: All Periods 700 lbs
- 10533 Rockfish Conservation Area: fishing restricted to inside 30 fm north of 43° N, restricted to inside 20 fm from 42° – 43° N
- 10534
- 10535 **2009**
- 10536 Other Nearshore Rockfish landing cap: 14.3 mt (excluding tiger and vermillion rock-fishes)
- 10537
- 10538 Other Nearshore Rockfish Period Limits: All Periods 700 lbs
- 10539 Legal Gear Types: hook-and-line (including pole and line, troll, longline, and stick gear) and pot gear (max 35 pots) if a Developmental Fisheries permit for Nearshore species using pot gear was issued in 2003
- 10540
- 10541
- 10542 Rockfish Conservation Area: fishing restricted to inside 30 fm north of 43° N, restricted to inside 20 fm from 42° – 43° N
- 10543
- 10544 **2008**
- 10545 Other Nearshore Rockfish landing cap: 12.0 mt (excluding tiger and vermillion rock-fishes)
- 10546
- 10547 Other Nearshore Rockfish Period Limits: All Periods 700 lbs
- 10548 Sorting Requirement for All Nearshore Rockfish to Species: first year of all nearshore rockfish recorded to species on commercial fish tickets
- 10549
- 10550 Rockfish Conservation Area: fishing restricted to inside 30 fm
- 10551 **2007**
- 10552 First year of commercial landing caps (formerly known as harvest caps)
- 10553 Other Nearshore Rockfish landing cap: 12.0 mt (excluding tiger and vermillion rock-fishes)
- 10554
- 10555 Other Nearshore Rockfish Period Limits: All Periods 600 lbs
- 10556 Rockfish Conservation Area: fishing restricted to inside 30 fm
- 10557 9/1: Other Nearshore Rockfish changes: Period 5 increase to 700 lbs; Period 6 increase to 700 lbs
- 10558
- 10559 11/28: Other Nearshore Rockfish change: Period 6 closed
- 10560 **2006**
- 10561 First and only year with 1-month trip limits
- 10562 Other Nearshore Rockfish harvest cap: 13.5 mt (including tiger and vermillion rock-fishes)
- 10563

- 10564 Other Nearshore Rockfish 1-month Period Limits: All Periods 200 lbs per month  
10565 Rockfish Conservation Area: fishing restricted to inside 30 fm  
10566 7/1: Other Nearshore Rockfish change: July increase to 300 lbs  
10567 8/11: Other Nearshore Rockfish changes: increase to 350 lbs per month for all remain-  
10568 ing months
- 2005**
- 10569 Other Nearshore Rockfish harvest cap: 12.0 mt 16.0 mt (excluding tiger and vermillion  
10570 rockfishes, 13.5 mt including these fish)  
10571 Other Nearshore Rockfish Period Limits (Sub-limit from black and blue Rockfish trip  
10572 limits): (includes tiger and vermillion rockfishes, sublimit of black and blue Rockfish  
10573 limit): All Periods: 450 lbs  
10574 Rockfish Conservation Area: fishing restricted to inside 30 fm  
10575 5/1: Other Nearshore Rockfish changes: Periods 3 thru 5 decrease to 325 lbs  
10576 10/11: Other Nearshore Rockfish changes: Period 5 and 6 increase to 400 lbs
- 2004**
- 10577 Permit required for vessels to land black and blue rockfishes and other nearshore fish  
10578 identified in House Bill 3108  
10579 Nearshore logbook required for all vessels participating in the fishery  
10580 ODFW allowed to prescribe legal gear under this permit except: 1. Diving gear may not  
10581 be used 2. Pots may not be used unless a vessel was previously issued a pot endorsement  
10582 in the Interim Nearshore Fisheries Plan through the Developmental Fisheries Program  
10583 during 2003  
10584 Other Nearshore Rockfish harvest cap: 16.0 mt (including tiger and vermillion rock-  
10585 fishes)  
10586 Other Nearshore Rockfish 1-month Period Limits (Sub-limit from black and blue Rock-  
10587 fish trip limits): (includes tiger and vermillion Rockfish), All Periods: 450 lbs  
10588 Rockfish Conservation Area: fishing restricted to inside 30 fm  
10589 9/28: Other Nearshore Rockfish change: Period 5 decrease to 100 lbs  
10590 11/1: Other Nearshore Rockfish change: Period 6 closed
- 2003**
- 10591 Commercial Nearshore Fishery (21 nearshore species) placed in the Developmental  
10592 Fisheries Program  
10593 House Bill 3108 establishes formal management of the commercial nearshore fishery,  
10594 comprised of landings of species on the 'nearshore fish' list beginning, January 1, 2004  
10595 Oregon Fish and Wildlife Commission first establishes harvest caps for nearshore  
10596 species: Other Nearshore Rockfish harvest cap: 21.3 mt

10600 Bi-monthly trip limits first put into place mid-season (July 16th) in 2003  
10601 Other Nearshore Rockfish (Sub-limit from black and blue rockfish): All periods 300  
10602 lbs  
10603 Rockfish Conservation Area: fishing restricted to inside 27 fm from January – October

10604 **2002**

10605 In October, the Pacific Fishery Management Council adopted conservative harvest  
10606 limits for 2003 equal to landings from 2000  
10607 Oregon Fish and Wildlife Commission directs the Marine Resources Program to eval-  
10608 uate a harvest reduction equal to or greater than 20  
10609 Interim commercial harvest management plan implemented place a cap on fishery par-  
10610 ticipants and reduced the nearshore fleet by 50  
10611 National Marine Fishery Service begins collecting fishery-dependent data at-sea from  
10612 vessels participating in the fishery

10613 **2000**

10614 Pacific City Open Access Minor Nearshore Rockfish Limit (including black and blue  
10615 rockfish here): May 1 - September 30 limit 2,200 lbs per month of which no more than  
10616 700 lbs can be rockfish other than black and blue rockfishes

10617 **1997**

10618 New live fish markets in California accelerate growth of the Commercial Nearshore  
10619 Fishery

10620 **Early to mid 1990s**

10621 Commercial Nearshore Fishery develops as an open access fishery

10622 **California**

10623 The following commercial regulations pertain to China rockfish species in California and  
10624 were provided by the California Department of Fish and Wildlife. There has been a 12 inch  
10625 minimum size limit on China rockfish since 2001.

10626 **Gear Restrictions**

10627 **2001**

10628 hook-and-line limited to 150 hooks with 15 hooks per line within 1 mile of shore

10629 **1996**

10630 Finfish trap permit required

- <sup>10631</sup> **1994**  
<sup>10632</sup> Proposition 132 implemented to prohibit gill nets within state waters
- <sup>10633</sup> **1953**  
<sup>10634</sup> Legislation prohibits trawl within 3 miles of shore
- <sup>10635</sup> **Trip Limits and Depth Restrictions**
- <sup>10636</sup> Trips limits now vary according to constraints from bycatch of canary and yelloweye rock-fishes
- <sup>10637</sup>
- <sup>10638</sup> **2003**  
<sup>10639</sup> A shallow nearshore permit is needed in 4 management regions  
<sup>10640</sup> Trip limits for restricted access fishery, with differential trip limits north and south of  
<sup>10641</sup> 40°10' N  
<sup>10642</sup> Subject to depth restrictions consistent with the shoreward non-trawl RCA
- <sup>10643</sup> **2002**  
<sup>10644</sup> Closed all waters January and February south of 34°27' N  
<sup>10645</sup> Closed all waters March and April between 40°10' N and 34°27' N March-April
- <sup>10646</sup> **2001**  
<sup>10647</sup> Closed January and February outside of 20 fm south of 34°27' N  
<sup>10648</sup> Closed March and April all waters between 40°10' N and 34°27' N
- <sup>10649</sup> **2000**  
<sup>10650</sup> Closed January and February south of 36° N  
<sup>10651</sup> Closed March and April between 40°10' N and 36° N
- <sup>10652</sup> **1999**  
<sup>10653</sup> Nearshore fishery permit required
- <sup>10654</sup> **1994**  
<sup>10655</sup> Limited entry permits and open access fishery established for *Sebastodes* complex  
<sup>10656</sup> Limited entry and open access trip limits on the *Sebastodes* complex
- <sup>10657</sup> **Nearshore Fishery Bycatch Permit** This special non-transferable permit is issued as of  
<sup>10658</sup> 2003 to those qualifying individuals who use either trawl or entangling nets (gill nets). It  
<sup>10659</sup> allows a minimal bycatch of minor nearshore species (which includes China rockfish) as per  
<sup>10660</sup> the following:
- <sup>10661</sup> South Central Coast Region 25 pounds of nearshore fish stocks may be taken per trip  
<sup>10662</sup> South Coast Region – 50 pounds of nearshore fish stocks may be taken per trip  
<sup>10663</sup> No permits are issued for either the North Coast or North-Central Coast Regions.

**10664 Appendix H. Recreational Regulations Histories**

**10665 Washington**

**10666** The following recreational regulations pertain to nearshore rockfish species in Washington  
**10667** and were provided by the Washington Department of Fish and Wildlife. The sport regula-  
**10668** tions run from 1 May to 30 April the following year. Depth restrictions were implemented  
**10669** late in the summer of 2005 by emergency rule and became permanent in 2006.

**10670 North Coast (MCA 3 and 4)**

**10671 2014-2013**

**10672** May 1 - Sept 30: Groundfish retention is prohibited seaward of 20 fathoms except  
**10673** lingcod; Pacific cod and sablefish on days open to halibut fishing

**10674 2012-2011**

**10675** June 1 - Sept 30: Groundfish retention is prohibited seaward of 20 fathoms, except on  
**10676** days open to halibut fishing

**10677 2010-2009**

**10678** May 21 - Sept 30: Groundfish retention is prohibited seaward of 20 fathoms except on  
**10679** days open to halibut fishing

**10680 2008-2007**

**10681** May 21 - Sept 30: Groundfish retention is prohibited seaward of 20 fathoms

**10682 2006**

**10683** May 21 - Sept 30: Rockfish and lingcod retention is prohibited seaward of 20 fathoms

**10684 South Coast (MCA 2)**

**10685 2014-2013**

**10686** March 18 - June 15: Groundfish retention is prohibited seaward of 30 fathoms except  
**10687** rockfish; Pacific cod and sablefish allowed May 1 June 15; lingcod allowed on days  
**10688** open to halibut

**10689 2012-2011**

**10690** March 18 - June 15: Groundfish retention is prohibited seaward of 30 fathoms except  
**10691** rockfish; Pacific cod and sablefish allowed May 1 June 15; lingcod allowed on days  
**10692** open to halibut

**10693 2010-2009**

**10694** March 18 - June 15: Groundfish retention is prohibited seaward of 30 fathoms; Pacific  
**10695** cod and sablefish allowed May 1 June 15

**10696 2008-2007**

**10697** March 18 - June 15: Groundfish retention is prohibited seaward of 30 fathoms; Pacific  
**10698** cod and sablefish allowed May 1 June 15

**10699 2006**

**10700** March 18 - June 15: Rockfish and lingcod retention is prohibited seaward of 30 fathoms

**10701 Columbia River (MCA 1)** This area has no depth restriction.

**10702 2014-2006**

**10703** Year-round: No groundfish except Pacific cod and sablefish allowed with halibut on  
**10704** board

**10705 Daily Groundfish and Rockfish Limits**

**10706** Groundfish includes: rockfish, Pacific cod, flatfish (except halibut), lingcod, ratfish, sablefish,  
**10707** cabezon, greenling, sculpins, sharks, skates, and surfperch excluding shiner perch. There are  
**10708** sub-bag limits for lingcod (2) coastwide and cabezon (1) in Marine Area 4. The groundfish  
**10709** daily bag limit in Marine Area 4B was reduced to 10 in 2011.

**10710** Groundfish Daily Limits

**10711** **2015-2011:** 12 fish

**10712** **2010-1961:** 15 fish

**10713** **1960-1938:** 20 lbs/day

**10714** Rockfish Daily Limits

**10715** There is no minimum size limit for rockfish. Marine Area 4B bag limit allows retention of 6  
**10716** blue and black rockfish only (2010-2015).

**10717** **2015-1995:** 10 fish

**10718** **1994-1992:** 12 fish

**10719** **1991-1961:** 15 fish

**10720** **1960-1954:** 20 lb/day

**10721 Oregon**

**10722** The following regulations pertain to nearshore rockfish species in Oregon and were provided  
**10723** by the Oregon Department of Fish and Wildlife. There were no bag limits prior to 1976.  
**10724** Gear restrictions have remained the same for all years, i.e., three hooks.

- 2015**
- All rockfish, greenlings, Cabezon, skates, and other marine fish species not listed in the 2015 Oregon Sport Fishing Regulations in the Marine Zone: 7-fish daily bag limit in aggregate, of which no more than three may be blue rockfish and no more than one may be a Cabezon (when Cabezon is open), and no more than one may be a canary rockfish.
- Retention of Yelloweye, Canary, China, Copper and Quillback rockfish is prohibited.
- 2014 - 2013**
- Same a 2012
- 2012**
- Rockfish, Cabezon, greenlings (10" min.), and other marine species not listed under Marine Zone in the Oregon Sport Fishing Regulations: 7 daily in aggregate of which no more than 1 may be a Cabezon April 1 – Sept. 30.
- 30-fathom curve: Seaward closed April 1-Sept. 30 [for groundfish group].
- 2011**
- Rockfish, Cabezon, greenling (10" min.), and other marine species not listed under Marine Zone in the Oregon Sport Fishing Regulations: 7 daily in aggregate of which no more than 1 may be a Cabezon April 1 – Sept. 30
- 40-fm curve: Seaward closed April 1-Sept. 30
- 7/21: Offshore of 20-fm line closed due to yelloweye rockfish impacts
- 8/13: Groundfish retention with nearshore halibut (central coast) prohibited
- 10/1: All depths reopened for groundfish (yelloweye rockfish impacts sufficiently slowed); Groundfish retention with nearshore halibut allowed again
- 2010**
- Same as 2009 including "rockfish" et al bag limit: 7 (misprinted in regulations booklet as 6)
- Definition of "groundfish group" added
- 7/24: Offshore of 20-fm line closed through Dec. 31 due to yelloweye rockfish impacts
- 2009**
- Same as 2008 through April 30 (adopted late), then increase in "marine fish" bag limit
- Rockfish, Cabezon, greenling (10" min.), and other marine species not listed: 6
- 40-fm curve: Seaward closed April 1-Sept. 30
- 5/1: "Rockfish" et al. bag limit increased to 7 (in permanent rule)

**2008**

10759 Same as 2007

10760 7/7: "Rockfish" et al bag limit reduced from 6 to 5 and closed outside 20-fm line through Dec. 31 [sic – see 9/7 change] and flatfish closed outside 40-fm line through Dec. 31 [sic]

10763 9/7: Return to preseason regs., i.e., "rockfish" et al bag limit back to 6 and waters closed offshore of 40-fm line only through Sept. 30 (open offshore Oct-Dec)

**2007**

10766 Rockfish, Cabezon, greenling (10" min.), and other marine species not listed: 6

10767 40-fm curve: Seaward closed April 1-Sept. 30

**2006**

10769 Rockfish, Cabezon, greenling (10" min.), flounder, sole and other marine species not listed: 6

10771 40-fm curve: Seaward closed June 1-Sept. 30

**2005**

10773 Rockfish, Cabezon, greenling (10" min.), flounder, sole and other marine species not listed: 8

10775 40-fm curve: Seaward closed June 1-Sept. 30

10776 7/16: Rockfish et al. bag limit reduced to 5

10777 10/18: Black RF prohibited for boats, Groundfish closed seaward of 40 fm

**2004**

10779 Rockfish, Cabezon, greenling (10" min.), flounder, sole and other marine species not listed: 10, no more than 1 P. Halibut

10781 Retention of yelloweye rockfish and canary rockfish prohibited

10782 40-fm curve: Seaward closed June 1-Sept. 30

10783 9/3: Rockfish, lingcod and greenling prohibited

**2003**

10785 Rockfish, Cabezon, greenling, flounder, sole and other marine species not listed: 10, no more than 1 Canary RF, 1 Yelloweye RF and 1 P. Halibut

10787 11/21: ocean closed to GF outside 27-fm line

**2002**

10789 Rockfish: 10, no more than 1 Canary RF and 1 Yelloweye RF

**2001**

10791 Rockfish: 10, no more than 1 Canary RF

**10792 2000**

10793 Rockfish: 10, no more than 3 canary RF

**10794 1999-1994**

10795 Rockfish: 15, no more than 10 black rockfish

**10796 1993-1986**

10797 Rockfish, Cabezon and greenling: 15

**10798 1985-1979**

10799 Other fish: 25, no more than 3 lingcod, 2 halibut and 15 rockfish/Cabezon/greenling

**10800 1978**

10801 Other fish: 10 Then effective 4/1 = - other fish: 25, no more than 3 lingcod, 2 halibut  
10802 and 15 rockfish/Cabezon/greenling

**10803 1977**

10804 Other fish: 25, no more than 5 lingcod and 2 halibut

**10805 1976**

10806 Other fish: 25

**10807 California**

10808 The following regulations pertain to nearshore rockfish species in Oregon and were provided  
10809 by the California Department of Fish and Wildlife. In 2000, a 3-hook and 1-line gear re-  
10810 striction was enacted. As of 2001, the gear restriction is 2-hooks and 1-line per angler. The  
10811 general rockfish (Rockfish/Cabezon/Greenling as of 2002) bag limit was 15 fish statewide  
10812 in 1999. As of 2000, it is 10 rockfish. The nearshore rockfish bag limit is the same as the  
10813 general rockfish bag limit except in 2003 and 2004. In 2003, the nearshore rockfish bag limit  
10814 was 2 fish south of Cape Mendocino in 2003 and for a portion of 2004.

## CDFW Recreational Season Lengths and Depth Restrictions for Select California Groundfish (1999-2014)

The following are summarized recreational season and depth limit regulations for select California groundfish from 1999 through 2014, including most inseason changes. Information was compiled from California's sport fishing booklet and supplemental booklets, as well as some emergency rulemakings.

Nearshore rockfish is defined as: black, black-and-yellow, blue, brown, calico, China, copper, gopher, grass, kelp, olive, quillback, and treefish rockfishes.

Shelf rockfish is defined as: bocaccio, canary, cowcod, widow, yelloweye, yellowtail, shortbelly, bronzespotted, chameleon, chilipepper, dwarf-red, flag, freckled, greenblotched, greenspotted, greenstriped, halfbanded, honeycomb, Mexican, pink, pinkrose, pygmy, redstripe, rosethorn, rosy, silvergrey, speckled, squarespot, starry, striptail, swordspine, tiger, and vermillion rockfishes.

**Key:**

	Allowed in all waters		
20	Depth closed greater than 20fm		
30	Depth closed greater than 30fm		
40	Depth closed greater than 40fm		
50	Depth closed greater than 50fm		
60	Depth closed greater than 60fm		
30-60	Depth open between 30-60fm		
	Closed	depth	In-season change
			In-season closure

### CALIFORNIA RECREATIONAL REGULATORY HISTORY, 1999

#### Statewide

#### California/Oregon Border to California/Mexico border

Species	Jan	Feb	Mar	Apr	May	Jun	July	Aug	Sep	Oct	Nov	Dec
Nearshore rockfish, California scorpionfish, California sheephead, Cabezon, Greenlings (rock, kelp), Ocean whitefish, Shelf rockfish, Lingcod, Sanddabs

California scorpionfish, Ocean whitefish	20	20									20	20
California sheephead												
Cabezon, Greenlings (rock, kelp)											20	20
Shelf rockfish <sup>3</sup> , Lingcod <sup>3</sup>												
Sanddabs												

**Notes for 2001:**

1. Emergency action was taken by the Commission in order to conform to federal regulations; closures did not apply to shore-based anglers.
2. Inseason emergency closure on October 29 prohibited angling for shelf and slope rockfishes and lingcod. Possession of these fishes was prohibited in state waters. In waters less than 20 fathoms, fishing for nearshore rockfishes, California scorpionfish, cabezon, and greenlings continued to be permitted (including waters around offshore rocks and islands less than 20 fathoms). Fishing for California sheephead continued to be permitted in all waters except the Cowcod Conservation Areas.
3. On January 1, 2000 the California Fish and Game Commission adopted regulations to be effective through 2002 that closed lingcod, nearshore, and shelf rockfishes as follows: south of Lopez Point to the Mexico border Jan. - Feb.; and north of Lopez Point to Cape Mendocino Mar. - Apr. New regulations that superceded the regulations adopted January 1, 2000 went into effect Mar. 5, 2001. These new regulations included a different regional management boundary between the central and southern management areas – Point Conception instead of Lopez Point. Because of the delay in implementation (March instead of January), the area between Lopez Point and Point Conception was closed from Jan. 1 - Feb. 28, 2001 (as part of the southern area under the 2000 regulations). This area then was open to fishing from March

Version 05/21/15

Figure H3

1- 4, 2001 (as part of the 2000 open fishing period for the southern area). However, once the 2001 regulations took effect on Mar. 5, 2001, this section of coast was closed again from Mar. 5 – Apr. 30 (as part of the central area under the 2001 regulations).

---

## CALIFORNIA RECREATIONAL REGULATORY HISTORY, 2002

Shelf rockfish <sup>2</sup> , Lingcod <sup>2</sup>							20	20	20	20		
Sanddabs												

#### Notes for 2002:

- Inseason emergency closure took effect for greenlings on July 1, cabezon on July 29, and California sheephead on November 1. Closures do not apply to shore-based anglers, or spearfishing from shore or a man-made structure.
  - The emergency closure for shelf rockfish, lingcod, California scorpionfish, and ocean whitefish went into effect July 1. Nearshore fishing was still allowed in waters shallower than 20 fathoms for nearshore rockfishes, California scorpionfish, and ocean whitefish. There was a special allowance for two shelf rockfish ONLY if taken incidental to nearshore fishing in less than 20 fathoms EXCLUDING bocaccio, canary, cowcod, and yelloweye rockfish, which could not be taken.
  - Management Area boundaries changed January 10, 2002.
-

**Notes for 2006:**

1. Inseason change on March 28 decreased the fishing depth limit from 40 to 30 fathoms in the Northern management area, and opened the months of November and December to recreational fishing (except for lingcod which was closed).
  2. Inseason change on March 28 kept depth limit at 20 fathoms in the North-Central and Monterey South-Central management areas, but opened December to recreational fishing (except for lingcod which was closed).
  3. Inseason change on July 1 liberated the fishing depth limit from 20 fathoms to 30 fathoms in the North-Central and Monterey South-Central management areas (except for lingcod which was closed).
  4. Inseason change on July 1 opened October to recreational fishing in the Morro Bay South-Central management area.
  5. Inseason change on March 28 allowed recreational fishing in the Southern Management area during October (with 30 fathom depth limit), November (60 fathom depth limit), and December (60 fathom depth limit), except for lingcod which was closed to all fishing.
  6. Inseason change on July 1 liberated the fishing depth limit from 30 fathoms to 60 fathoms in the Southern Management area for the remainder of the season (except for lingcod which remained closed in December).

**Notes for 2011:**

1. As part of the biennial management specification process, the North-Central North of Point Arena Management area was renamed the Mendocino Management Area, the North-Central South of Point Arena Management Area was renamed the San Francisco Management Area, and the Monterey South-Central and Morro Bay South-Central Management Areas were combined into the Central Management Area.
2. Due to a delay in the federal regulatory process, recreational regulations for 2011 in California did not go into effect until June 11, 2011.

Lingcod			60	60	60	60	60	60	60	60	50	50
Sanddabs												

**Notes for 2012:**

1. Sub-bag limit for greenling increased from two fish to 10 fish within the 10 fish daily RGC bag limit.
  2. High encounter rates for cowcod in the SMA lead to inseason action to restrict anglers' maximum fishing depth from 60fm to 50fm.

**Notes for 2014:**

1. Based on projected estimates for 2014, it was predicted that the California scorpionfish annual catch limit would be exceeded unless closed. Thus, in-season action was taken to close the fishery from November 15 through the end of year.
